The Southern Ry. is making extensive improvements at its Finley Yards, Birmingham, and it is understood will add car-building and repair shops at a cost of \$5,000,000, though no official confirmation has been given of the extent and nature of the work now under way.

Investigation by the Shelby County Grand Jury into the recent mutiny of convicts in the Montevallo Mines, operated under lease with convict labor by Messrs. Thomas and Weller, absolved the officials and warden of blame in the matter and recommended the restoration of the lash as a last resort in the punishment of unruly prisoners. Equipment in the mine was damaged to the extent of more than \$25,000 by dynamite in the hands of the convicts.

The large frame commissary building and contents at the Mary Lee Coal Mine of the Alabama Company, was destroyed by fire Feb. 2 with a heavy loss. The origin of the fire is unknown. The building will be replaced.

The Youngstown Mining Co., of Blount County, has increased its capital stock from \$2,000 to \$300,000 in accordance with papers filed with the Secretary of State at Montgomery. The incorporators are W. H. Young, H. M. Norwood and J. A. Simpson, of Birmingham.

It is reported that the Brilliant Coal Co. will make another opening at Calumet, Walker County, and will construct a number of tenant houses in connection with the new development. The offices of the company are in Birmingham.

Charles H. Nesbitt, for the past twelve years chief mine inspector for Alabama, serving under the appointment of the three previous governors, has been reappointed for a term of four years by Governor Brandon. Through an increased appropriation by the last Legislature Mr. Nesbitt expects to extend and perfect the work of his department so as to render the service much more valuable to the mining industry during the next four years.

The Birmingham office of the Sullivan Machinery Co., of Chicago, has been removed to 2108 5th Avenue North, where ample ground floor space provides more adequate accommodation for the company's business. G. P. Small is local manager for Alabama.

William Goodwin, of Birmingham, W. P. Smith, Rock Castle, and George Kuffner, Kellerman, have been named associate mine inspectors for a term of four years by Governor Brandon.

ILLINOIS

The Peabody Coal Co. operating and engineering department heads from all over the country assembled in the annual operating conference at Chicago Feb. 4 and 5. Various problems of management and production were discussed.

Federal stamps placed on the deed of the transfer of the Bickett Coal & Coke Co. mining property in Franklin County, to the Franklin County Coal Co., formerly the Taylor Coal Co., represented \$1,200, indicating a value of the total properties at \$1,200,000. The papers were recently drawn up by Marion Hart, attorney at Benton, the land being located near Royalton, in that county.

Fred Truebger, assistant engineer for the Union Colliery Co. at its Kathleen mine, at Dowell, has been made civil engineer, succeeding Arthur S. White, of Chicago, who held the position for the past three years.

Julius F. Yarp, for some time assistant to the commissioner of the Chicago Coal Merchants' Association, has been appointed commissioner, succeeding Colonel A. C. Earnshaw, who has resigned.

The Lumaghi Coal Co. has reopened its No. 3 mine, at Collinsville, after a six weeks shutdown.

C. E. Campbell, of the Consumers Company of Chicago, joins the Globe Coal Co., wholesalers, of Chicago, April 1.

New electrical equipment now being installed in Old Ben mine No. 16, at Sesser, is almost completed and will be in use in a short time.

INDIANA

The Consolidated Collieries Co., of Indianapolis, has been incorporated to deal in coal and other fuels and to operate mines. The company has a capital of \$25,000. Roy C. Bain, Warren F. Smith, and James E. Bingham are directors of the company.

Judge John E. Cox, of the Superior court, Terre Haute, has named Clem Richards receiver for the Burnett Coal Co. (the Devonald mines), and fixed his bond at \$25,000. The receiver was named on the application of the Mid-American Mutual Casualty Co., which carries the mine compensation. The mines were recently operated by a group of miners as a co-operative project.

The Dixie Vein Coal Mining Co., Indianapolis, with a capital of \$50,000, has been incorporated. Jacob S. White, Burrell Wright and Paul Kirk are the directors of the company. The Dixie Vein mine near Terre Haute, closed for 18 months, will soon be reopened.

IOWA

The Shuler Coal Co., while drilling on the W. A. Snyder farm, two miles east of Alpha, where their mine is located, struck a vein 5 ft. 4 in. thick.

The property of the Consolidated Coal Co. at Buxton, has been disposed of in a trade to Gavrousky & Goldstein, of Centerville, for a 323-acre farm in the northern part of Appanoose County, and other considerations. The Buxton property consists of a tract of farm land, the large company store and several other buildings. Coal mining has been abandoned on the property and it will now be used for other purposes.

Joe Pestotnik, one of the veterans in the coal mines of Boone, recently received a wage check for \$205.98 for eleven and one-half days work. This is the record wage check received at Boone.

KENTUCKY

Senator Bannie Tabor's scrip bill, passed in 1922 and lost before it was enrolled, has been passed again by the Kentucky Senate, and will undoubtedly become a law. The bill provides that persons, firms and corporations which issue scrip must redeem it at face value for any person presenting it. The bill is to prohibit speculation in scrip, and to prevent mine-operating companies from being able to buy it up at a percentage of its value.

The Dawson Daylight Coal Co. of Dawson Springs, controlled by the K. U. Meguire interests, Louisville, plans to start loading coal from its new stripper operation within about thirty days.

MISSOURI

John A. Sargent was made a vice-president in charge of the coal department of the Central Coal & Coke Co., Kansas City, by the directors at a meeting Feb. 6. Since July 20 Mr. Sargent has been general manager of the coal department of the Central, and had been acting manager of the department since the resignation, Feb. 1, 1923, of Harry N. Taylor, vice-president in charge of the coal department, to become president of the United States Distributing Corporation. Before Mr. Taylor's resignation Mr. Sargent was sales and traffic manager of the Central.

The sale of the Blackfoot coal mine, at Prathersville, by the receiver, S. F. Conley, to W. R. Prather, who for several years has been manager of the mine and a large stockholder, has been approved by Judge David H. Harris of the Circuit Court. The mine is one of the largest in the county and the coal is mined with the aid of electrical machines.

John Mammen has purchased a steam shovel and will use it in mining coal on his farm, northeast of Golden City. Mammen has a large acreage of surface coal and his new equipment will enable him to do a much larger business.

NEW YORK

Lieutenant Eugene C. Roberts, of Buffalo, who has been second in command of Troop A, state police, has resigned his position and will go into the coal trade, in which he was formerly engaged. He and his two brothers, Paul and Clark T., have formed the Roberts Coal Co., which will have headquarters in Detroit, Mich. They will handle both coal and coke at wholesale and also represent the "Electric Furnace-man." The three young men are sons of Eugene C. Roberts, a member of the Hedstrom coal concern, Buffalo.

OHIO

The work of organizing the Columbus-Pocahontas Coal Co., of Columbus, incorporated three months ago with a capital of \$300,000 is progressing satisfactorily, according to F. A. Garen, and the work of developing a large property in the smokeless field will be started. Chicago capitalists are interested in the new company.

The Fuel Sales Co., Canton, has been chartered with an authorized capital of 5,000 shares, no par value designated, to produce, buy, sell and deal in coal and other minerals for fuel. Incorporators are E. L. Hang, Edward Reiser, H. S. Roose, J. R. Beiter and E. A. McCuskey.

The Whitesburg Coal Co.'s branch office in Cincinnati has been closed after a year's participation in the trade there. The Old Dominion Coal Corporation has reopened its Cincinnati office with N. K. Howard in charge. The Riddle Coal Co. has opened a branch office in Cleveland.

Harry Young, head of the Utilities Coal Co., of Huntington, Ind., was in Cincinnati recently and has arranged to take over the output of the Harlan Coal Co., at Ages, Ky., and the J. L. Smith Coal Co., at Draper, Ky., by the Kearns Coal Co. Both produce about ten cars a day each. Mr. Young will become a member of the Kearns concern and will retain his Indiana headquarters.

The Ogle Coal Co. has taken offices in the new Frederick H. Schmidt Building, Cincinnati. Several changes have been made on the eighth floor of the Dixie Terminal. The Creech Fuel Co. and the Wallins Creek Coal Co. have changed their locations.

After being idle for several months, work was resumed at the Palos mine, near Glouster, but a fire destroyed the power house, throwing 100 men out of work again. The loss was about \$30,000. Steps will be taken to repair the damage at once.

OKLAHOMA

The Grace B. Mining Co. has been organized at Picher to develop raw coal lands owned by this company in that immediate vicinity. The company is capitalized at \$300,000 and incorporators are D. O. MacKaller, E. L. Morris and A. C. Wallace, all of Picher. The company has under lease and owns in fee considerable coal lands in the vicinity of Picher and it is planned to develop these lands at an early date.

The John T. Cole Mines Co. has been organized at Schuler for the purpose of developing extensive coal lands. The company is capitalized at \$50,000 and the incorporators are John T. Cole, A. M. Cole and I. W. McAllister.

PENNSYLVANIA

There were 506 fatalities in the anthracite mines of Pennsylvania in 1923, according to a preliminary report of Joseph J. Walsh, Secretary of Mines. This total is said to be smaller in proportion to the number of miners employed and the number of days the mines operated than during any period in the past fifty years. The actual number of fatal accidents was larger, however, than in some of the recent years. Secretary Walsh said, but when the number killed was smaller the number of workers employed and the number of working days were smaller. The fatalities occurred in fifty-six of the 137 companies operating in Pennsylvania last year. Seventy per cent of the accidents occurred before noon, Mr. Walsh pointing out that the morning period of work is that of the greatest activity. The preliminary report classifies the causes of accidents as follows: Falls of roof and rock, 221; crushed or killed by cars, 63; gas explosions, 43; premature blasts, 46; crushed or killed by machinery, 12; miscellaneous, 121. Of those killed 245 were miners; 83, miners' laborers, and the others were employed in various other capacities. Approximately 160,000 miners in the anthracite region worked an average of 273 days last year.

City Purchasing Agent Lafferty, of Philadelphia, has awarded contracts aggregating more than \$1,016,282 for furnishing coal to the various municipal bureaus for the current year. The amount of the award made to each of the successful bidders was: Philadelphia & Reading Coal Co., \$750,000; Bell Coal Co., \$71,500; Jenkins & McCall Coal Co., \$64,000; George B. Newton Coal Co., \$62,250; Mason-Scholes Coal Co., \$60,750; E. O. Kelly, \$4,500, and John C. Hancock Co., \$3,282.

The H. C. Frick Coke Co. fired 1,000 additional beehive coke ovens last month and is firing 1,000 more this month, and a number of other companies in the Connells-ville district also are increasing their output or are preparing to do so. The Hillman Coal & Coke Co. has fired the balance of its idle ovens at the Isabella plant and all the ovens at the Tower Hill No. 2 plant which had been idle since last autumn. There are 254 rectangular ovens at this plant. The Etna-Connellsville Coke Co. is getting ready to start its plant at Simpson with 119 beehive ovens; W. J. Parshall is doing the same at his 100 beehive oven plant near Uniontown. Both these plants have been idle since autumn.

The state tax collected on anthracite this year on last year's business, based upon reports so far filed with the Auditor General's department, will reach \$6,000,000 to \$7,000,000, fiscal officers of the state contend. Approximately 250 anthracite producing companies will file reports. Several of the large producers who have filed reports sold more coal despite strike conditions last year than in 1922. The period for filing the reports ended with the close of January, but owing to details connected with the making up of the reports Auditor General Samuel S. Lewis has granted extensions of fifteen days in most cases.

A state charter has been issued to the **Jordan Coal Co., of Scranton**, with a capital of \$50,000, the purpose of which is to buy, own, sell and operate coal lands. William R. Willis, Pershing, is treasurer, and the three incorporators are William Mack, Scranton; Albert Zenke, Scranton, and F. R. Jordan, Hazleton.

The **Pittsburgh Coal Co. Employees' Association** reports that the total of employees' savings and investments through the association during the year 1923 was \$492,099.46, of which \$361,359.13 was by mine employees in the Pittsburgh district. During the year 1923 1,901 employees contracted to purchase 11,906 shares of stock; 5,027 shares of stock were delivered to 598 employees on completed contracts; 2,384 employees received \$1 per share additional to the dividends for the year, authorized by the directors of the company to be paid to employees and or their dependents holding stock of the company purchased through the Employees' Association. Since this association was organized 26,872 shares of stock have been delivered to employees on completed contracts.

John Barnes, Barnesboro (Cambria County) coal operator has become the owner of the **Tobias Mishler farm** of 263 acres near Red Bridge, now Kring's Station, in Conemaugh township, Somerset County. The tract is underlaid with valuable coal deposits and has been the object of attention of coal operators for many years. Acquisition of the tract is taken to mean that a huge coal operation will soon be started with a town on the level lands bordering on the river.

State charters have been issued at Harrisburg to the following coal companies: **Pennsalt Coal Co., Natrona**, mining and preparing coal for the market. Capital \$25,000. Incorporators: Warner T. Over, 1435 Cayuga Street, Philadelphia, treasurer; Charles M. Butterworth and L. A. Smith, Philadelphia. **Tyrone Coal Co., Uniontown**, \$30,000, mining and preparing coal for the market. Incorporators: George H. Bortz, Uniontown, treasurer; Anton Luxner, Dawson, and Charles E. Bortz, Uniontown. **Stevens-Chapin Coal Co., Wilkes-Barre**, which will mine and prepare coal for the market. The company's capital stock is \$25,000. Nat D. Stevens, 800 East Main Street, Nanticoke, is treasurer and one of the incorporators, the others being Ernest M. Chapin, Brookline, Mass., and James R. Scouton, Wilkes-Barre.

The **H. H. Robertson Co.**, manufacturers of Robertson process asbestos protected metal, skylights, ventilators, mineral rubber and special asphalts, has announced the appointment of James S. Ervin, formerly in charge of the sale of mineral rubber and special asphalts, as manager of sales, with headquarters at Pittsburgh, to succeed C. D. Mercer, resigned.

WASHINGTON

Announcement has been made at Longview by the **American By-Products Co.** of the incorporation of a \$2,000,000 corporation which plans to develop the byproducts of the Cowlitz County coal fields, the building of a 250-ton commercial plant on the Cowlitz River two miles north of Longview and Kelso, and the ultimate intention to serve this district with gas. Purchase of the coal deposit, estimated as containing 20,000,000 tons, will involve the expenditure of \$1,000,000.

Clarence L. Wickstrom, mining engineer of Spokane, and associates recently bought an interest in the **Beacon Coal Co.** of Allentown, of which he has been made manager. In discussing the deal Mr. Wickstrom said: "The company has three seams of coal of workable width, 10,000,000 tons blocked out above the tunnel level, a property valuation in excess of \$1,275,000 and nothing to sell but its products. But besides coal and coal residuum these products include benzol, gasoline, gas ammonium sulphate, tar, creosote oil, lubricating oil and pitch, all produced from the coal with the Green-Lacks process, equipment for the use of which the property is supplied."

WEST VIRGINIA

The **R. S. Lumber & Coal Co.**, of Martinsburg, has just been organized, with a capital stock of \$25,000. Interested in the new concern are J. P. Rensburg, of Capon Bridge; R. A. Snyder, of Markleton, Pa.; I. D. Van Meter, of Kearneysville, Pa.; G. J. Shaffer and G. P. Morrison of Martinsburg.

That it is unlawful to employ a boy under 16 years of age in the mines or elsewhere in West Virginia is the substance of a decision of the West Virginia Supreme Court in connection with the damage suit of Ray Jackson against the **Monitor Coal & Coke Co.**, originally tried in the Logan Circuit Court, the plaintiff asking damages of \$25,000. The court held among other things that "such employment is not rendered lawful by the fact that at the time of his employment the boy misrepresented his age; nor by the employer requesting and receiving from the county superintendent of schools and keeping on file, a certificate showing that such child is over 16 years of age."

A tippie at Wilmoth, in the Barbour County field, was destroyed by fire late in January. The large coal bin, being full of coal, also burned and continued to burn for several days. Only a few men were at work when the fire occurred, but preparations were being made to operate on a larger scale.

There were 36 deaths incidental to the mining of coal in and around West Virginia mines during the month of December, 26 being due to fall of roof and coal and 5 being due to mine-car accidents. McDowell County mines had 9 fatalities; Fayette had 6 and there were 3 each in Logan, Mingo, Monongalia and Raleigh; 2 each in Brooke and Kanawha, and 1 in Boone, Marion, Mercer, Nicholas and Wyoming.

Frank L. Bowman, at the head of several companies operating in the Monongalia field and with headquarters at Morgantown, has announced his candidacy for the Republican nomination for Congress in the Second West Virginia district.

A three-year old fire in the mine of the **A. L. Black Coal Co.** near Maidsville not only threatens to destroy all the coal in a 14-acre tract of Pittsburgh coal owned by the company but also is menacing adjoining mines in the same region. Unless it is possible, according to W. B. Rigglesman, State Mine Inspector, to confine the fire to the 14-acre tract, it may spread into the adjoining operation of the **Warner Collieries Co.** In order to prevent the spread of the fire, fourteen brick walls are being rushed to completion by a force of twenty-five men, through the construction of which it is hoped to cut off the supply of oxygen from the Black mine and thus cause the fire to extinguish itself. The fire broke through the outcrop on Feb. 6, great sheets of flame ascending from the outcrop and dense clouds of smoke enveloping the community in which the fire has been raging. As showing that it has sought in every way possible to protect its own interests as well as the interests of other mines, the **A. L. Black Coal Co.** states that it has spent between \$50,000 and \$60,000 in endeavors to control the fire and has done everything that expert advice seemed to direct in an effort to control and extinguish the flames.

WYOMING

J. H. Slate, a mining engineer from Pittsburgh, has been making a thorough inspection of the **Conroy coal mine**, situated about nine miles north of Kemmerer, it is reported on good authority, to reopening the mine at an early date. Slate was shown the interior workings of the mine by Joe McDonald, who has been in charge of the property since it was shut down several years ago, and he is convinced that coal can be mined and marketed profitably. If this meets with the approval of the Pittsburgh owners of the mine it is practically certain that operations will be resumed during the coming summer.

WASHINGTON, D. C.

The United Mine Workers, it is announced, are preparing to fight Governor Pinchot's coal bill as introduced in Congress by Senator Borah. It is declared the measure aims at anti-strikes and for that reason organized labor is against it. An official of the miners in Washington is quoted as opposing the bill because it would tie up the funds of the organization and threatens to jail the officers. The bill provides that in the event of an emergency growing out of a strike threat the president may exercise through a proposed coal division of the Interstate Commerce Commission all the powers conferred by the Lever act in effect during the war. The courts have interpreted this act as giving the authorities power to enjoin the calling of a strike in any industry affecting the nation's fuel and food supply.

CANADA

The **Coalmont Colliery, in the Princeton coal field of British Columbia**, has opened a new 14-ft. seam of high-grade bituminous coal, and, as a consequence, is increasing its working force. The coal from this mine is in demand in the city of Vancouver, which is capable of absorbing the whole of the output of the mine.

The **Crows Nest Pass Coal Mining Co.** has found it necessary to close down "B" North and No. 1 North mines, owing to the slackness of trade. This is unusual at this time of the year and is attributed to the competition of fuel oil and the Fordney tariff.

Coke-oven gas from the new \$2,500,000 plant of the By-Products Coke Oven Co., Hamilton, Ont., was turned into the mains recently. The city's supply has thus been increased 1,500,000 ft. a day. Some 200 men are at work in the plant. An effort will be made to use Nova Scotia coal.

Edward T. Devine, a member of the U. S. Coal Commission, in a public address in Toronto recently said that instead of the United States putting an embargo on coal shipments to Canada, it should be encouraging exports to the Dominion and extending its market there. He stated that the United States still had large coal reserves and, if mining could be carried on steadily, could produce half as much coal again with the same number of miners. Exports to Canada are comparatively small.

Following the announcement of the reorganization of the **Western Fuel Corporation of Canada, Ltd.**, which has large coal mine holdings on the east coast of Vancouver Island, mainly centered in and around the Nanaimo, B. C., a group of financiers of San Francisco and Los Angeles, Calif., have been visiting and inspecting these mines and properties. At the head of the party was Guy H. Kinsley, of Peirce, Fair & Co. The corporation now has a capitalization of \$5,000,000 divided into 1,000,000 8-per cent cumulative preferred shares of \$1 each and 4,000,000 common shares of \$1 each. The new company is assuming the present bond issue of the old company of \$3,000,000, which is secured by trust deeds held by the Montreal Trust Co.

The **City of Nanaimo is facing what may prove a serious problem.** It is built on old coalmine workings and a short time ago a cave-in occurred in a residential section and water began to seep through to the surface. An effort was made to drain it but it continued to rise until there was danger that a firehall would be flooded. The city council then closed the block affected to traffic and, in the meantime, an effort is to be made to locate the workings, of which no reliable maps are available, with a view to filling them in and taking whatever other measures may be found necessary to protect city property.

New Equipment

Automatic Suction Valve for Mine Gathering Pumps

This valve is to control automatically the suction inlet of a plurality of suction connections on mine pumps, and eliminate the necessity and expense of valve operators. The elimination of the hand-operated system of suction control makes it practical to pump from a number of places at the same time, which permits a considerable reduction in the size of branched suction pipes without sacrificing economy. From an efficiency standpoint automatic suction control approximates the equivalent of reaching all the water through a single suction connection for each pump because of the fact that all the pumps have access to all their water at any and all times through these automatic valves.

These valves are designed to work anywhere in a branch suction between the point of branch and the water to be pumped. They are simple and rugged in construction, having no levers or floats. Each valve is a complete unit within itself and is not dependent on any mechanism whatever at the source of water. The valves are of the diaphragm type and are automatically opened by the pump suction against a spring by a vacuum of about $\frac{1}{4}$ lb. per square inch when the suction inlet is submerged. They are closed by the spring when the water is lowered sufficiently to allow the system to begin to receive air.

The entrance of air into the valve weakens the vacuum in the vacuum chamber, causing the opening of a vent valve to the atmosphere, which immediately destroys the vacuum under the diaphragm, allowing the spring to close the valve without hesitation. The opening again of the main valve is dependent on the sealing of the suction inlet with water and the return of the vent valve to its seat, the latter being controlled by a mechanical time-limiting device which can readily be adjusted to suit conditions in the place to be pumped.

Automatic Suction Valve

Each valve on the system operates to cut off its suction as soon as the water has been pumped down in its sump. When the water fills up again the valve automatically reopens.

This valve has been developed by C. E. Rogers, electrical engineer for the Logan Mining Co., Logan, W. Va., and is being manufactured by Dravo Doyle Co. of Pittsburgh, Pa., and marketed by the Rogers Manufacturing Co., Logan, W. Va.

110-Volt Light and Power Plant

A new 110-volt direct-current light and power plant, manufactured by the Westinghouse Electric & Mfg. Co., has been developed to solve the problem of supplying current for light and power in locations where central-station service is not available. The plant consists of a gasoline engine, electric generator, and electric starter and control all built into a single, compact unit. It

Small Light and Power Station

This engine develops 3 hp. and is suitable for direct-lighting service or for charging the batteries so as to provide for heavy lighting or power drafts.

also includes a battery in which to store the electricity from the generator. The fact that the engine is air cooled makes possible its installation in an unheated outhouse.

This light and power plant supplies ample energy for the operation of electric lights, small motors for various needs, water-pressure pumps, buzz saws and similar mechanical appliances. It is economical in fuel and oil consumption, and its slow operating speed and rugged construction provide for long life and dependable service under

the most rigorous conditions.

The plant operates on either gasoline, kerosene or natural gas and is particularly suitable for mine service in regions remote from electric-lighting lines and also for emergency service.

Either of two batteries may be had with the unit. One has a

capacity of 7,850 watt-hours at 8-hour rate and the other has a capacity of 15,750 watt-hours at 8-hour rate.

The single-cylinder four-cycle engine has a bore and stroke of $3\frac{3}{8} \times 5$ in. A fan in the flywheel draws air into the cylinder dome and over the cylinder fins, assuring cool operation under all conditions. The engine is lubricated by a splash feed system which supplies an equal amount of oil to the moving parts at all times, regardless of the depth in the crankcase.

The 1,500-watt four-pole generator, which is bolted to the engine frame, is of the sleeve type on the engine shaft. It has a shunt winding and a series field to start the engine.

Low-Rate Battery Charger

The Magnar battery charger, a device marketed by the General Electric Co. for the "trickle" or "floating" charging of railway signal batteries, is being applied to new fields, such as time clocks, bell systems, burglar alarms and tripping batteries in power plants and substations. It has been found that on such installations the batteries may be discharged continuously at a very low rate or intermittently at a higher rate, the average discharge rate being low in either case.

By the "trickle" or "floating" charge method the charging equipment operates continuously. The average rate at which the battery discharges being first determined, the equipment is regulated to supply the battery just enough current to compensate for the discharge plus a small additional quantity to allow for internal leakage. Among the advantages claimed for this method of charging are the continuous maintenance of a fully charged battery, a constant voltage, longer life and the necessity of a minimum amount of attention.

For hoisting signal service on the many shaft and slope hoists of the coal mines this device no doubt will meet with favor because it eliminates the necessity for dangerous high-voltage signal systems and obviates the need for continual attention and renewal of batteries of the primary or secondary type.

Charger for Small Batteries

Number 9

Energy or Atrophy?

THREE years of peace in the bituminous-coal industry! Shall they be years of construction or deterioration? Shall the companies energize or atrophy? In these years of peace is a chance for notable constructive work. In fact it may be said that only those companies which confront the situation boldly now and bring their mines up to the best practice devised or projected will be able to sail through the three years of peace, weak market and competition. Only those who modernize their mines—who in 1924 do all they can to cheapen their ways of operation—will see 1927. If nothing is done, if their owners “wait and see,” the mines may endure but the properties will change hands.

Some will hope to win by heartening their sales force by cutting salaries and by discharging a man here and there at the office and the mine, but only by radical improvements at the mines can the true solution be found. Cheaper coal, obtained by better machinery and by a cutting down of risks, will alone work the reformation. What improvement is made must needs be fundamental. No half measures will serve. The result will be obtained not so much by removing needed officials, repair and maintenance men but by the broader policy of providing mechanical appliances that will actually make men superfluous.

It will be necessary to remember that the mine is the fighting front. The comforts of the rearguard must be renounced and the fight must be pressed where the victory alone can be won—at the face—not forgetting of course the necessity of providing the necessary finances for the needed mine equipment.

Hoodlumism

ONE day a cloud of dust swept aggressively up the road into a troublesome Colorado coal camp. A lean-jawed ranger on a motorcycle burst out of it and halted in front of a crowd of scowlers. “I hear somebody in this town said he was gonna get the first ranger that come in. Where’s that man?” he demanded. The scowlers swallowed and blinked. Some appeared to shrink back. “I don’t think nobody said that,” finally offered somebody. “All right then,” replied the ranger. The cycle roared, the dust cloud rose, and he was gone but not forgotten. That town remembered such occurrences.

What if the Kluxers and the Knights of the Flaming Circle and the rest of them down in Herrin, Ill., had some such remembrance? Would there be so many hot guns and so many fresh graves and such hell on earth for the decent citizens of Williamson County? But they have no state rangers in Illinois. One of the reasons why they haven’t is that organized labor killed the constabulary bill in the last session of the State Legislature.

Violence has come to be a habit in the solidly unionized coal field of “Bloody Williamson.” The spirit of

disregard for law has grown up there among a large number of men who have let powerful unionism go to their heads. There are good, sound, sane citizens among the union miners of that territory, just as there are in every other union field, but the isolation of the region from every interest but the unionized production of coal has given too many of those men the idea that the law of the union, which has made them dominant in their neighborhood, is the only law worth obeying. Some of them are getting wobbly about obeying even that.

Union propaganda blamed bolshevism for the 1922 outbreak of these men—the infamous Herrin massacre. Bolshevism can hardly be blamed for the moonshine war of this year. It is due to just plain lawlessness of mind—the same inflamed mental attitude which led to the butchery of twenty-two non-union men in Herrin two years ago. Only one thing will help to check it—outside control. Sending in troops periodically is clumsy. The only form of outside control worth a whoop is offered in the form of a state constabulary. Such a force is needed so badly that even the mine workers’ union could benefit by its suasion. Rangers, by inspiring more respect for statute law in the minds of Williamson County miners, might evoke more respect for union law. There were indications at the Indianapolis union convention and elsewhere that union law is suffering from lack of respect in Illinois. Hoodlumism is bad for any union. Mr. Lewis and Mr. Farrington might bear this in mind when the next constabulary bill comes up in Illinois.

The Union Will Learn

“WE ARE weak; we can’t fight now,” was the doctrine preached to the United Mine Worker delegates at the Indianapolis convention. So they sent their men to Jacksonville pacifically minded. The delegation was pacific enough in its attitude there. Unionism did not need to wave a bludgeon. Nobody stoutly demanded that miners take a cut in wages. Nearly everybody but the operators from Illinois were reasonably willing to give the miners what they asked—a four-year continuance of the present scale. And the trimming of that program to three years was made principally because Illinois gagged at the dose, feeling that the program is nearly suicidal. But is it?

Of course, many a coal company will have to retire from the field. But with them must go an army of union miners. This means further weakness of the union. The first thing to expect of those discolored miners is that they travel over into non-union fields and try to remain in the kind of labor they know and like.

They may be good union men but they must live and they will go where they can work even if it be into non-union territory, just as hundreds of them did during the 1922 strike. This gives the non-union operator a higher hand. Likewise, it gives the union operator more opportunity to select the men he wants to keep,

which means an increasing opportunity to run his own property instead of letting unionism run it as is generally the case in many union fields.

What does all this mean? Doesn't it mean that an already weakened union is going to be compelled to recognize the fact that union-field wages must be adjusted downward if union coal is to keep any of its markets and continue in production? That is exactly what it means. President Lewis could not propose it to his men now. The rank and file would strike. A strike would be ruinous to all unionism and all union fields. Therefore the rank and file must learn of its necessity through bitter experience.

The bitter experience is now starting. Every mine shutdown makes the bitterness more poignant. The natural result of it all is an appeal by the union for a change in the wage agreement. Some day such an appeal will be made by the union by the exercise of nothing but plain common sense—unless government intervention or some other extraneous influence can be dragged in by Mr. Lewis.

Much at Little Cost

SUCH a small concession to public need and private virtue is federal inspection! One is almost ashamed to suggest so little to those who have done so much. If we had argued that the anthracite region spend \$5,000 or \$6,000 per day for inspection of its own and had urged that coal that did not meet the needs of that inspection should go back to the breaker and be treated again till it met with specifications, that would have been asking a sacrifice indeed. We are sure that the anthracite region would have demurred. "Two millions a year! Preposterous!" would have been the cry.

If we had argued that the railroad coal companies should sell their coal under the market price, taking no advantage of the fact that other companies were selling for much more, we should have been regarded as hopeless idealists.

But these things have been done, are being done. The second is so unusual, so self-denying, that the public persistently doubts that it *is* being done and tries to suggest it is a trick of which some secret, subtle advantage is being taken.

Yet when we argue that the federal government should inspect cars here and there at its own expense and see if those that have no inspection and those that have are alike producing coal of the specification now demanded we are told by some that it is too much. This little dip into Jordan, this ceremonial washing is too great a concession, we are told, to be taken by men who made such magnanimous provisions as those for an elaborate self-inspection of every car and a regulation of prices on all the domestic sizes sold.

No one can explain the difference except that the distinction is a "Little thing but mine own." The anthracite companies made their own big concessions, but this one is suggested to them without ostentation by a federal bureau, and consequently they demur about it. We cannot see why.

But is this concession little—if concession it may be termed? Surely it gives the public such assurance of right dealing, such an advertisement of rectitude of purpose that though it cost nothing it will do more to establish the anthracite industry in the good will of the public than either or both the concessions already

made. It will earn the public good will; it will promote the public confidence. At a time when oil is getting into public reprobation, and for good reason, coal will come back as have the railroad and central-station industries. Why not make the venture, if venture it be?

All Soft-Coal Mines Are Powder Magazines

RECENTLY a soft-coal mine superintendent in asking a question said incidentally that his mine was a safe one. We have forgotten where the mine was. It was not, however, in the anthracite region, so we were confident that it was a powder magazine and liable, if he did not take precautions—unusual precautions—to explode. He has a dangerous mine and we did not fail to tell him so. If the public fools itself that any of the bituminous mines are safe from explosion it is deceived, unless indeed the mine has been made safe by diligent stone dusting.

In the Ruhr the operators at last are beginning to see that humidification is at best only a palliative. It has done much to make the mines safer, but rock dusting is a greater security, and at that it must be thorough. Great Britain with its 50-per cent admixture of stone dust has altogether too many explosions; the Belgian and French rule of requiring 70 per cent of inert material seems preferable.

Unfortunately, in the United States the cars are built up with lumps, and the coal in consequence rolls off the cars whenever brakes are applied to either the locomotives or the cars. In this way the roads are strewn with material which soon is ground to an explosive dust. So long as the practice continues a road treated with rock dust inevitably will soon be rendered dangerous. Loading machines with or without conveyors will largely correct that condition because the best that can be done economically with a loading machine is to load the coal "baldy," or with only a rounded top. When the brakes are applied on such a car it will merely shake down, leaving the coal still in the bed. Furthermore, by concentrating operation proper treatment of the few roadways involved will be a job well within economical possibility.

At the mines of the Phelps Dodge Corporation in New Mexico all the cars are lightly loaded. In consequence the coal-dust evil is reduced to a minimum. This company also is going heavily into the practice of rock dusting. Shelves 2,000 ft. in length have been introduced to carry rock dust or adobe and the same material is being spread by the cement gun and other methods. The Old Ben Corporation also is using rock dust generously to protect its mines.

The movement is spreading. No one wants to have a mine bespread with a material that is and has been frequently used as constituent for the manufacture of a low-grade but extremely effective explosive, unless indeed that constituent is guarded by some inert material.

THERE IS CO-OPERATION IN COAL NOW, if there never was before. Those numerous bituminous-coal operators who have contended that the industry needed only a long period of low market to eliminate the unfit and thereby correct many coal evils have long had the co-operation of heavy storers, of smooth-running railroads, of plenitude of labor and even of the Great Operator himself, who has modified the winter thus far to a degree seldom exceeded.

One More Mechanical Loader Comes to Light

Wilson Chainloader for Low Coal Weighs 4,600 Lb.
and Has Maximum Height of 32 In.—It Has Loaded
69 Tons of Coal a Day and 120 Tons of Loose Gob

AROUND the corner of almost every gob pile in the American coal fields somebody is quietly developing an underground coal loader. It is no surprise, then, to learn that F. N. Wilson, of St. Louis, Mo., working under the paternal interest of the Southern Coal, Coke & Mining Co., of that city, now has what he calls the Wilson Chainloader fairly well developed after nearly two years of experimentation and back-breaking work. This machine, the appearance of which is suggestive of the Joy loader but which differs from it in many respects, is now working in one of the Bell Coal & Navigation Co.'s mines near Sturgis, Ky., under the inventor's eye and hand.

W. F. Davis, general superintendent for the Southern Coal, Coke & Mining Co., said early in January that the machine "is handling a clod and bastard lime, heavily shot, of course, to make it as small as possible, at the rate of 15 tons an hour." The machine has been loading coal also. On 12-ft. entry work, where, of course, it was handicapped by narrowness just as any loader would have been, it has loaded about 30 tons a day, but in 25-ft. rooms its best day was Aug. 29, 1923, when it loaded out 69 tons. This work was in coal not exceeding 40 in. in thickness.

The machine in its present form is designed especially for use in thin coal. It stands 32 in. high from the rail to the highest point on the machine—a sprocket on

the top of the upper end of a sloping conveyor. It is possible that this height can be further reduced to 28 in. The machine today therefore can load under a roof approximately 36 in. above the rail. It weighs about 4,600 lb.

The Chainloader is made up of two conveyors and the mechanism that drives them, all mounted on a four-wheel self-propelled truck, the wheelbase of which is 48 in. long. The main conveyor is 12 ft. long and slopes at an angle of about 18 deg. when the front end is lowered to the floor in operating position. It pivots at the back and can be swung through an arc with a front-end cord of 16 ft. Coal is gathered onto this swinging conveyor and delivered at the top of the machine to a non-adjustable conveyor which extends horizontally backward over the car to be loaded. The machine is driven by three motors—one of 7½ hp. actuating the gathering arms and main conveyor, one of 2 hp. affording traction and the third, of 2 hp., operating the rear conveyor.

The digging and gathering of the coal to the main conveyor is done by two kinds of arms—two heavy digger bars and a series of conveyor arms. The digger bars remind one of the flails which operate on the Joy machine, although there are important differences. Thus they are neither jointed nor flexible. One of these digger bars is mounted at each side of the front end of the conveyor pan or tread plate. It is about 6 ft. long and made from tool steel 2 in. square. The front end is curved in sickle shape and is pointed. Just back of this curve the bar is attached to a crank disk by

The headpiece shows the Wilson Chainloader, which is designed for thin coal. This machine has been working in a 40-in. seam and, without reducing its present maximum height of 32 in., could load coal in a 36-in. deposit. This picture gives some idea of the main conveyor with the two digger bars and the conveyor arms.

a substantial tool-steel pin. The crank disk moves the front end of the bar in an elliptical path, the plane of which is slightly above that of the conveyor.

Not only does this bar move with a gathering motion, dragging coal to the conveyor, but it also rotates through 90 deg. This is accomplished by reason of the fact that 28 in. of the bar's rear end is turned to 2 in. in diameter and provided with rifled grooves $\frac{3}{4}$ in. deep on opposite sides. These grooves, which engage heavy pins, run straight along the bar except at their forward ends, where they follow a helical course for a sufficient distance to impart a 90-deg. rotation to the bar.

This twisting motion of the digger bar turns the "sickle" up when it reaches a position directly over the conveyor. This permits lump coal of good size to pass under the bar and reduces the likelihood of its dragging coal off the conveyor.

Actual conveyance up the tread plate is accomplished by two endless chains fitted with arms which extend 14 in. across the 18-in. plate. These arms are attached to the links of each chain at 36-in. intervals and are so arranged as to alternate with each other. Thus the arms are 18 in. apart as they move up the tread plate pushing coal to its top. Roller chain of 3-in. pitch is used on this conveyor.

Each conveyor arm is built of a $\frac{1}{4}$ -in. steel strap 3 in. wide lying on edge. Two pieces of this flat steel are placed approximately on the two sides of a right-angle triangle of which the chain forms the third side. A link attachment secures the two corners of the arm to the conveyor chain, and a certain amount of flexibility in the arm itself allows it to negotiate the sharp turn which the chain makes in rounding the sprockets at the ends of the conveyor.

MACHINE WILL CLEAN A WIDE AREA

A "machinery plate" which in shape resembles a wide T that lies flat on top of the truck, with the cross of the T at the forward end, forms the base of the entire machine. The rear end of the main conveyor pivots directly above the base of this T-shaped plate. Most of its weight rests on the cross of the T, on which a curved track is mounted. The forward end of the conveyor is supported on deeply grooved wheels running on this track and swings through its 16-ft. arc, enabling the machine to clean up a fairly wide area.

In practice the machine is moved up to the front of a fall of coal. One man with a crowbar easily swings the front end of the conveyor to the extreme left of its arc. The machine then begins work along the left rib. The traction motor crowds it into the pile of coal. As soon as the pile at that point is reduced so that the right-hand digger bar is doing the heaviest work the action of this bar tends to pull the end of the conveyor under the coal. By releasing a chain, a few inches at a time, the operator permits this swinging

motion to proceed until the loader has swung through its full arc. A man with a crowbar then swings it back to the left, the machine is crowded forward again, and cuts another swath through the pile. Thus the operation is repeated. The inventor asserts that this machine can clean up a place so neatly that little or no hand shoveling is necessary.

Originally the machine was built with one continuous conveyor which flattened down at the back. However, Mr. Wilson soon concluded that there were many advantages in breaking the long conveyor into two separate sections. Not the least of these was the advantage of always having the tail end of the machine lined up

with the car to be loaded. Consequently the present machine has a flat delivery conveyor 8 ft. 6 in. long suspended from the rear of the loader frame. This conveyor is built up in a peculiar manner. A belt 30 in. wide is riveted to thin iron cross slats which are attached at their ends to roller chains of $\frac{3}{4}$ -in. pitch. Both the main and delivery conveyors move at a speed of 300 ft. per minute.

During the two years of experimentation that have

F. N. Wilson

Inventor of the Wilson chainloader

passed since W. K. Kavanaugh, president of the Southern Coal, Coke & Mining Co., first saw a model of this machine operating in Mr. Wilson's basement in St. Louis many a "bug" in this loader has been eliminated. When the long tread plate of the main conveyor buckled it was made rigid by a long angle iron riveted underneath. When the conveyor arms snapped under the strain of revolving around the sprockets their design was changed. Spur-gear drives were replaced by worm gears working in oil. The main motor of 25 hp. was replaced by one of $7\frac{1}{2}$ hp., which appears to be ample. Over-all height was reduced by changing from 4-pole motors to 2-pole.

Other improvements followed one upon another until today the machine is able to stand considerable rough-and-tumble work though it is not yet ready for extensive commercial production. As this was written there also appeared to be some likelihood of patent infringement difficulties although the main patents covering the machine all have been allowed by the Patent Office, and their holders are ready to rise in their defence.

The Machine is Merely Two Conveyors

The main conveyor can be swung through an arc of 16 ft. to clean up a considerable area. The rear belt with its riveted cross slats of iron always is in line with the car being loaded.

RENEWING THE SALT LOST IN PERSPIRATION.—In England, Professor Moss of the University of Birmingham, with the advice of Dr. Haldane, has made a study of the effects of chloride elimination during excessive sweating while working in high temperatures. He states that the addition of sodium and potassium chlorides to the drinking water materially lessens the muscular fatigue and prevents miners' cramps.

What Everyone in the Industry Should Know About Handling of Mining Machinery

Many Equipment Failures Due to Lack of Understanding of the Machines
—Devices Should Be Designed to Meet Mining Conditions— Proper
Performance Obtainable Only When Machinery Is Kept in Good Repair

By T. F. MCCARTHY

Electrical Engineer, Indiana, Pa.

IN THE evolution of mining methods which has been rapidly taking place our industry has seen a marked increase in the use of machinery. Much of the equipment now used has been developed for special application to mining service but a far greater proportion of the equipment now commonly used in or about the mine has been adopted from other industries.

The application of mechanical and electrical machinery has been so rapid that few except those who have an intimate contact with it have a proper appreciation of its important characteristics; in fact, many of those who have direct supervision of its operation have been unable to give it the care and attention ordinarily required. Another disadvantage most engineers have realized is the fact that machines introduced from other industries do not always withstand the hard mine service.

In spite of these adverse conditions the application of machinery is rapidly expanding, and it is therefore becoming increasingly necessary that mining men become more thoroughly familiar with mechanical and electrical machinery if the best results are to be obtained. It also is important that many manufacturers of equipment for mine service design their product or revise their designs to meet mining conditions.

Mine superintendents, foremen and assistant foreman usually have direct supervision of the operation, care and repair of mining machinery and it is therefore important that they be sufficiently familiar with the equipment to know its limitations and be able to ascertain whether or not it fits the conditions and is being given proper attention and repair. In this connection there are three important points to be considered, namely: The equipment must be designed for the particular operating conditions, it must be operated within its rating and must be properly cared for and repaired.

The question of design is a problem that requires special attention. Often mine equipment must operate in very damp and dirty locations and under widely different conditions, all of which must be taken into consideration. It is particularly important that motors and other electrical equipment be designed to keep out moisture and dirt. Haulage, cutting and hoisting equipment are subject to very heavy overloads, and due consideration must be given to the rating and capacity of the motors and the design must be such as to withstand severe mechanical stresses. It is therefore important that those responsible for the purchase of mine equipment remember that the operating conditions, rating and quality of the apparatus should govern its selection rather than first cost.

Many equipment failures are due to the operation of machinery under conditions different from those for

which it was designed. Motors often are operated on circuits where the voltage is too high or too low, and to avoid failures from this cause one should remember that the voltage of a circuit should never vary more than 10 per cent above or below that stamped on the name plate. Pumps often are operated on heads above their rating or the suction or discharge pipes are smaller than the openings on the pump, yet they are expected to deliver their rated capacity. These conditions apply to all classes of mine equipment and where a machine or motor is continually breaking down an investigation usually will reveal the fact that some condition is not right for its successful operation.

The largest percentage of equipment troubles are due to faulty lubrication and dirt. Every piece of apparatus requires certain grades of lubricating oils and greases for the different bearings. The manufacturers of equipment will gladly recommend the particular lubricant to use on their machines and these recommendations should be closely followed. With motors, an over-supply of oil frequently is the cause of electrical trouble. The excess oil gets into the windings and spreads itself over the insulation of the wiring, field coils, armature and commutator bars, causing the insulation to break down and resulting in a short-circuit. Oil mixed with dirt serves as a path for current to leak, thus causing burned insulation.

Repairmen should be thorough in the inspection and cleaning of equipment. If the machines are cleaned of excess oil and dirt at every inspection it will be possible to eliminate a large percentage of the most common troubles.

Haulage locomotives are one of the most abused classes of mine equipment. Those in charge do not know their limitations and as a consequence they are given very little attention. Locomotives usually are operated over poorly kept tracks and the supply voltage often is much lower than that necessary for successful operation. Some motormen believe a locomotive should haul any size trip that can be coupled to it.

A locomotive is guaranteed to deliver a given drawbar pull at a rated speed provided the track conditions and the voltage of the circuit are correct. A modern locomotive can be relied on to deliver a drawbar pull equal to 25 per cent of its weight provided the wheels can obtain sufficient adhesion to the rail. The tractive force therefore is governed by the size of rail and condition of the roadbed. If locomotives are to be expected to deliver their rated drawbar pull, heavy rails should be used and the track should be well kept. With chilled cast-iron wheels it is the usual practice to consider the drawbar pull equal to 20 per cent of the weight of the locomotive, while with steel tires the drawbar pull will be equal to 25 per cent of the weight

of the locomotive. It is necessary then, if we wish to obtain best results from our locomotives, that the load attached to the motor shall not cause it to exceed its rating and that the proper voltage be maintained on the trolley circuit.

Where plain-bearing mine cars are used it is common practice to consider 30 lb. per ton as the friction load and 20 lb. per ton as the grade resistance. For example, let us suppose it is required to determine the number of cars a 10-ton locomotive will haul on a 2-per cent adverse grade where the mine cars are equipped with plain bearings and the total average weight of the loaded car is two tons.

With a proper size rail—which should not be less than 40 lb. per yard—and the rated voltage on the trolley circuit, the correct number of cars for the trip will be determined as follows: The drawbar pull of a 10-ton locomotive with steel tired wheels is 5,000 lb. The friction load of the 2-ton car at 30 lb. per ton is 60 lb. per car. The grade resistance load at 20 lb. per ton is 40 lb. per car; the total drawbar pull per car is therefore 100 lb. As the drawbar pull of the locomotive is 5,000 lb. it is apparent that it can haul a load equal to fifty cars each weighing two tons. As the locomotive weighs ten tons and is therefore equal to five 2-ton cars, it is capable of hauling only forty-five cars of this given weight on the 2-per cent grade.

OPERATE LOCOMOTIVE MOTORS WITHIN RATING

The motors in a locomotive usually are guaranteed to deliver their rated drawbar pull at a given speed with a temperature rise not exceeding 75 deg. C. or 167 deg. F. over a period of one hour. If the load exceeds the capacity of the locomotive and the haul is long, the temperature may exceed the safe limit and the insulation of the armature and field coils become overheated. To keep within the rating of the motors it is necessary that the duty cycle of the locomotive

be such that during periods when the locomotive is lightly loaded, coasting or standing, it will have time to cool off.

A 25-per cent overload on a motor will reduce the time the motor attains its maximum temperature from one hour to one-half hour and also cause a reduction in speed of approximately 10 per cent. If the haul is long and the locomotive overloaded and there is not sufficient time between trips for the motors to cool the result will be overheating and insulation failure.

Another cause of trouble from overheating is low voltage. A 10-per cent reduction in voltage will cause a reduction in speed of approximately 20 per cent, causing an increase in the time required to make a trip and resulting in overheated motors, increased power consumption and reduced output. Low voltage usually is found to be due to poor bonding and lack of sufficient copper in the trolley or feed lines.

Overloads increase the demand charge with a resulting increase in energy cost. Low voltage also increases the energy cost because when the speed of a locomotive has been reduced 50 per cent the power bill is doubled and the extra power has been wasted in overcoming the resistance of the track, poor bonds or overloaded feed lines.

The motors of modern locomotives are equipped with ball or roller bearings which require a special grade of grease. Great care should be given to see that the bearing housings are dustproof and that no dirt is working into them. Journals and axle linings also require a special grade of oil and the oil wells should be kept packed with a good grade of wool waste and the lids properly fitted to prevent sand and dirt working into them.

All driving-gear bearings should be kept reasonably tight so that the gears will mesh properly. Gear cases should always be installed and kept tight and the gears lubricated with a gear compound. Brake rigging and

Underground Pumping

Some of the pumps used in the mines must be located in remote places, this is because the pump must be located where the water can be concentrated. Late developments in pumping machinery have resulted in odd looking pumping stations; motor-driven centrifugal pumps are sometimes seen with steam-driven reciprocating pumps.

shoes should be kept in perfect adjustment to prevent any possibility of accident.

Motor brushes require a certain amount of attention to see that they are seating properly and not sticking in the holders. Controllers should be inspected regularly and all fingers and segments that are burned or pitted should be promptly repaired and kept lubricated with a light coating of vaseline. The air gap between the motor armature and pole pieces should be regularly checked with a gage to make certain that the clearance is correct. Where compressed air is available it should be the practice to blow off all accumulations of sand and dirt at frequent intervals. This method of

Enclosed Type Motor

If manufacturers selling equipment to the mining industry would study the conditions under which their equipment must operate, far better success would be obtained. Enclosed motors will usually be much larger and more expensive than the open types but in many cases they would quickly prove more satisfactory.

cleaning is especially effective on the rheostat because it will clean off the grids and reduce the probability of short-circuits and grounds.

TWO TYPES OF PUMPING EQUIPMENT

Mine pumps may be divided into two types, reciprocating and centrifugal. When driven by means of an electric motor they are either direct-connected, belt driven or gear driven. The reciprocating type pump, either piston or plunger, generally is used for gathering purposes.

Whenever a pump is inspected the motor also should be inspected so as to be certain that the brushes are seating properly, are free in the holders and the winding and commutator are free from oil and dirt. If excessive sparking occurs at the motor it probably is caused by a dirty commutator, sticky brushes, open or short-circuited armature coils, partly short-circuited field coils or grounds. If any such defect is noted it should be given instant attention so that the source of trouble may be located.

The hand-operated or automatic starter also should be examined to see that it is functioning correctly and that all connections are tight. These starters have a definite purpose in the circuit, being used to accelerate the machine slowly, prevent excessive mechanical strains and also to prevent excessive starting current when the motor is connected to the line. Where hand starters are used the pumpmen or workmen often will tie the arm of the starter in the running position so that in the case of power failure they will not have to

return to the starter to put the motor in operation when power is again on the line. Men should be reprimanded or discharged for doing this, as they are defeating the purpose of the starter and frequently cause serious material damage or injury to other workmen. All motors should be properly protected by fuses of a carrying capacity low enough to protect the motor in case of trouble; ordinarily the fuses should not be more than 50 per cent in excess of the full load current of the motor.

The packing on the pump rods, plungers and pistons should be regularly examined and tightened or replaced when required. When a packing gland is tightened the handiest nut to get at is often turned down and the other one left loose. This causes the packing to bind and the rod to be cut or scored.

When the pump fails to pick up its water the valves should be examined to see that they are seating properly and that all bolted connections and suction lines are free from air leaks. Efficient strainers on the suction pipe will reduce the possibility of particles of coal or rock being carried into the pump and preventing the valves from seating properly. The connecting-rod bearings should be tightened before a knock develops. Where mine water is especially bad the water ends of the pumps should be made of an anti-acid composition or lined with wood or cement; ordinary cast iron will not successfully resist the action of an acid water.

Centrifugal pumps should be used only on heads very close to that for which they are designed, for ordinarily they have the peculiar characteristic of overloading when the head is too low and of not delivering their full capacity when the head is excessive. They also require that the suction line be absolutely airtight and the pump and suction line be primed before being started.

In the inspection of a centrifugal pump care should be taken to be certain that all bolted connections and packing glands are free from air leaks. Bearings should be examined to see that the oil reservoirs are properly filled and that the oil rings revolve freely. The inside of the pump should be examined occasionally to see that the wearing rings on the rotor and casing have a minimum clearance, because excessive clearance will permit too much water slippage and the pump will not deliver its rated capacity. The openings in the rotor may become plugged up with coal or wood, and

Cable Reel Locomotive

A locomotive which may be repaired easily is always better than one which the repairmen must tear down to make adjustments or changes.

therefore should be cleaned. The thrust bearing should be closely inspected and adjusted.

Cutting machines are required to operate under very adverse conditions of voltage and load, and as the dust conditions usually are abnormal they will prove very expensive to maintain unless carefully operated and repaired. Lack of proper lubrication is a prolific source of trouble. Very often the machine runner neglects to oil the machine when required and puts in an over-supply at long intervals of time instead of using a small amount of oil at frequent intervals. These machines require special grades of lubricants for the different bearings and drives and require particular care to prevent dirt from entering the bearings.

The hardness of the coal being cut determines the speed of the feed on the machine, and if the load on the motor is to be kept within its rating and the mechanical stresses within safe limits, the cutting speed must be correctly proportioned to the load. Manufacturers of cutting machines furnish different ratio gearing for the different feeds required, which makes it possible to make the rate or speed of the feed such that the load is within the capacity of the machine at all times. The machine runner always should be supplied with a sufficient number of sharp bits so that the used bits may be replaced when dull. Many overloads and burned-out armatures are caused by machine runners attempting to cut with dull bits.

ENCLOSED MOTORS BEST FOR HOISTS

Room-hoist motors require the same careful inspection and adjustment needed by other electrical equipment and should be specially protected from dampness because they operate very intermittently. The most suitable motor for this class of work is the totally enclosed crane type. When hoists are operated by unskilled labor it is necessary to see that the controllers or starters are in good and safe condition and that the motors are not overloaded by the men attempting to haul too many cars or replace heavily loaded derailed cars on the track.

Mine cars represent one of the largest investments in equipment about the mine and as a rule are expected to remain in operation without attention until worn out or put out of service due to a wreck. As the condition of the cars largely governs the output of the mine they should be regularly inspected and repaired so that the trucks will always be in perfect alignment and the friction reduced to a minimum. Ball and roller bearings have considerable merit and undoubtedly reduce car friction and are worthy of careful consideration in buying new equipment.

PROTECT WIRE ROPE AGAINST CORROSION

Other items used about the mines, such as wire rope, electric cables, drills and other accessories to mine equipment represent a considerable investment and their correct use is an important consideration in the successful operation of the mine. All wire rope used on cutting machines and hoists should be protected from corrosion by the application of a rope preservative or compound.

Trailing electric cable on cutting machines, cable-reel locomotives and other machines should have an insulation constructed so as to resist abrasion and moisture. Cables with molded rubber covering have proved quite successful for this service.

The Miner's Torch

Seeing Things

MAGAZINE and newspaper editors have an idea, I am told, that technical men are not competent to write descriptions dealing with plants or processes with which they are well acquainted, the argument being, of course, that they might leave out several important links in the narrative without realizing that the average layman cannot jump the gaps that are left. Since I class myself a "technical man," I might be accused of violating the proprieties if I questioned the editors' judgment in the matter, but by way of countering the accusation, I want to go on record as saying that the average layman or laywoman attempting a description of a plant or industry with which he or she is not familiar generally spoils the picture by saying too much. They do not leave any gaps to jump largely because they fill in all of the gaps with their own imaginings.

The January issue of *Success* magazine has an article which illustrates the point I am attempting to make. The article gives the impressions of a woman investigator who was sent to Alabama to investigate the operations of the Steel Corporation around Birmingham.

She describes what she saw and does it well, then she proceeds to tell about conditions as they were in the past, not as she saw them, of course, never having been in Alabama before, but as they were described to her by others. And you are left with the impression that all of the changes for the better date back only to the year 1907 when the Steel Corporation took charge of the properties.

I am sure that no one connected with the Steel Corporation consciously intimated that the mines in Alabama in 1907 were veritable hell holes and then overnight as they changed ownership or even in 16 years were transformed to their present state. Also I feel sure that the author of the article did not bring in these contrasts as overnight transformations just to make the article interesting but the result nevertheless is to make you doubt the accuracy of the entire description, and some might even wonder if the article was not inspired by the Corporation.

The conditions which she refers to as conditions of the past are not greatly exaggerated, and had the author only realized and made her readers realize that by past was meant thirty-five or fifty years ago, when the mines were first opened and that in a state where mining had never been carried on before, the impression made by her narrative would have been quite different.

The mining industry is in need of all of the publicity it can get; many of the editors and the politicians who take such delight in saying hard things about our mines and miners do not know that our country is filled with mining camps where the men and their families are well housed and otherwise treated as human beings—just as in the mining camp described in the article under discussion. What a pity then that the crude conditions of thirty-five years ago had to creep into the narrative to take hold of the reader's imagination.

I am reminded of the old saying that runs something like this: "It takes four very live men to carry out one dead man."

Valley Coals of Virginia Present Unusually Difficult Operating Conditions

Beds Are Located in Pocono Measures—Seams in Places Pitch so That Floor of Seam Is Higher Than Roof—As a Result of Pressure and Faulting Coal Often Is Badly Crushed

GEOLOGICAL conditions make the operation of the seams in Montgomery, Pulaski and Wythe counties, in Virginia, known as the Valley coal field, difficult to work and hard to clean. It also has crushed the coal. The seams are in measures below those of even the Pocahontas field, which lies a short distance to the north and west of the Valley region.

The coal beds of the region occur in the Price formation, the basal measures of the Carboniferous system, and they are therefore much older than the coal beds that lie farther northwest. The Price formation is of about the same age as the Pocono sandstone. Beds of this age carry coal in many parts of the northern Appalachian region, but, so far as known, they do not contain it in commercial quantities north of the Potomac River. Most of the beds that can be operated are limited to the counties of Virginia just named.

Montgomery County—In this county the coal lies in two distinct fields, as shown in Fig. 2, the Brushy Mountain field (A) on the north and the Price Mountain field (B) on the south. In the Brushy Mountain field only one bed (the Merrimac or "Big Bed") is generally of workable thickness. This bed extends entirely across the county on the south slope of Brushy Mountain. It dips to the southeast from 20 to 40 deg.

This coal, though locally much crushed, is generally workable from the New River eastward to a place about a mile beyond the Blacksburg-Newport road, but east of this place it has been crushed by movements within the crust of the earth, and in some places has been crowded into thick pockets and in other places almost squeezed out. Where the Merrimac bed is workable its thickness ranges from 5 to 9 ft., but it is broken by many bony partings, which are difficult to separate from the coal and which, if not removed, help to swell its already large percentage of ash.

COAL BEDS ARCH UPWARD TOWARD PRICE MOUNTAIN

The mine of the Superior Anthracite Coal Co. (5), which is a mile back from the river, at the station of McCoy, on the Virginian Ry., is the only one in the Brushy Mountain field that has direct railroad connection. In the autumn of 1923 four other mines—the mine of Linkous & Kipp (4), the College mine (3), the mine of the Diamond Coal Co. (2a), and the mine of the M. J. Shusser Coal Co. (3)—were working in a small way and trucking their output to Blacksburg for local consumption or for shipment on the railroad. Recently the A. Dunphy Coal Co. has begun operations on the property just south of that operated by the College mine (3).

The Price Mountain coal field (B) lies west of the road between Blacksburg and Christiansburg and com-

prises an isolated area of the Price formation that is entirely surrounded by the Valley limestone. Price Mountain, a small ridge about three miles long, has been formed by the arching up of the Price formation, so that the coal beds dip away from the axis of the arch in all directions and, in general, the accompanying beds of limestone dip correspondingly away from the mountain.

The dip of the coal beds on the south side ranges from 20 to 35 deg. and on the north from 30 to 50 deg. At some places on the north side the coal bed stands nearly vertical, and in some of the old mines it is reported to have been overturned so as to dip steeply toward the south.

As the beds of limestone and the coal bed have about the same degree and direction of dip, the coal bed obviously passes beneath the limestone in most directions, but the extent of the coal bed beneath the limestone is not known. As the coal bed in Price Mountain dips to the north and the same bed in Brushy Mountain dips to the south the logical conclusion is that the coal is continuous under the limestone from one outcrop to the other, but this assumed continuity can be proved only by drilling.

In general the limits of the coal fields of Montgomery County are determined on one side by the outcrop of the coal bed and on the other by the depth to which mining can be profitably carried. If 2,500 ft. is assumed to be the vertical depth to which mining can be made profitable, and if the dips range from 20 to 30 deg., then a strip of country ranging in width from three-quarters of a mile to 1½ miles may be regarded as containing minable coal. If the dip flattens with increase of depth the width of the belt of available coal will be increased.

This belt of available coal along Brushy Mountain is continuous across the county except in areas where the coal is crushed, but the coal in Price Mountain is limited mainly to its north and south sides, for at its ends the coal bed has been greatly crushed and faulted.

MERRIMAC MINE CONNECTS WITH TWO RAILROADS

Much coal has been mined in Price Mountain, but most of the mines have been small, and they have not extended any considerable distance beyond the drainage level. Only three mines are now in operation. The Merrimac mine of the Merrimac Anthracite Coal Corporation (6) is the largest and is the only one in the field that has direct railroad connection. It is favorably located for transportation, for it is on the south side of the mountain and has connections with both the Norfolk & Western and the Virginian railroads. The coal bed in this mine is from 5½ to 7 ft. thick and this thickness is typical of the bed on the Price Mountain field. The mine of the Brunfield Coal Co. (7) also is on the south side of the mountain, but it is small and its output is trucked to the railroad,

NOTE—This article is written from facts supplied by the U. S. Geological Survey. Wherever not declared to be based on report, the measurements given are those actually obtained by the geologists in charge of the Survey. A prior article, entitled "Can the Valley Coal Fields of Virginia Compete with Those of the Anthracite Region," appeared in the issue of Feb. 21 on pages 269-271.

half a mile distant. On the north side of the mountain a small wagon mine of the Eureka Coal Co. (8) supplies fuel for local consumption.

Pulaski County.—The coal fields of Pulaski County, as shown on the map (Fig. 2), consist of the Little Walker Mountain and the Pulaski fields.

The Little Walker Mountain field (c) is the south-westward continuation of the Brushy Mountain field of Montgomery County. The coal beds naturally extend from one field into the other, but the Merrimac bed appears to thicken to the west. The increase in thickness is generally believed to be due in large part to the greater number and increased thickness of the partings. The Langhorne bed ("Little Bed"), which normally lies 20 to 70 ft. below the Merrimac bed, also increases in thickness to the west and becomes 3 to 5 ft. thick in the western half of the Little Walker Mountain field. As this bed contains no bony partings its increase to workable thickness makes it very valuable, especially as its coal is somewhat harder than the average coal in the Merrimac bed.

The structural conditions in Pulaski County are much the same as those in Montgomery County except that

the coal beds dip more steeply, the dip ranging from 35 to 50 deg. Because of this increase of dip the width of the belt of available coal is narrow, only slightly exceeding 2,500 ft. in horizontal distance, which also is the limit of depth.

Two mines with railroad connections are operating in the Little Walker Mountain field—the Parrott mine of the Pulaski Anthracite Coal Co. (9), on the Norfolk & Western Ry. and the New River, and the mine of the Empire Anthracite Coal Co. (10), at the foot of Brushy Mountain, which connects with the same road at Pulaski, seven miles distant. The coal from the Empire mine (10) is hauled by tram to the breaker at Pulaski over part of an old railroad built many years ago by the Bertha Mineral Co. to their Altoona coal mine (11), about two miles west of the Empire mine. The Parrott mine (9) is operating in the Merrimac bed and the Empire mine (10) in the Langhorne bed.

COAL OUTCROP BENDS SHARPLY TO SOUTH

A short distance west of the old Altoona mine the outcrop of the coal bed leaves the slope of Brushy Mountain and turns sharply toward the east on the north

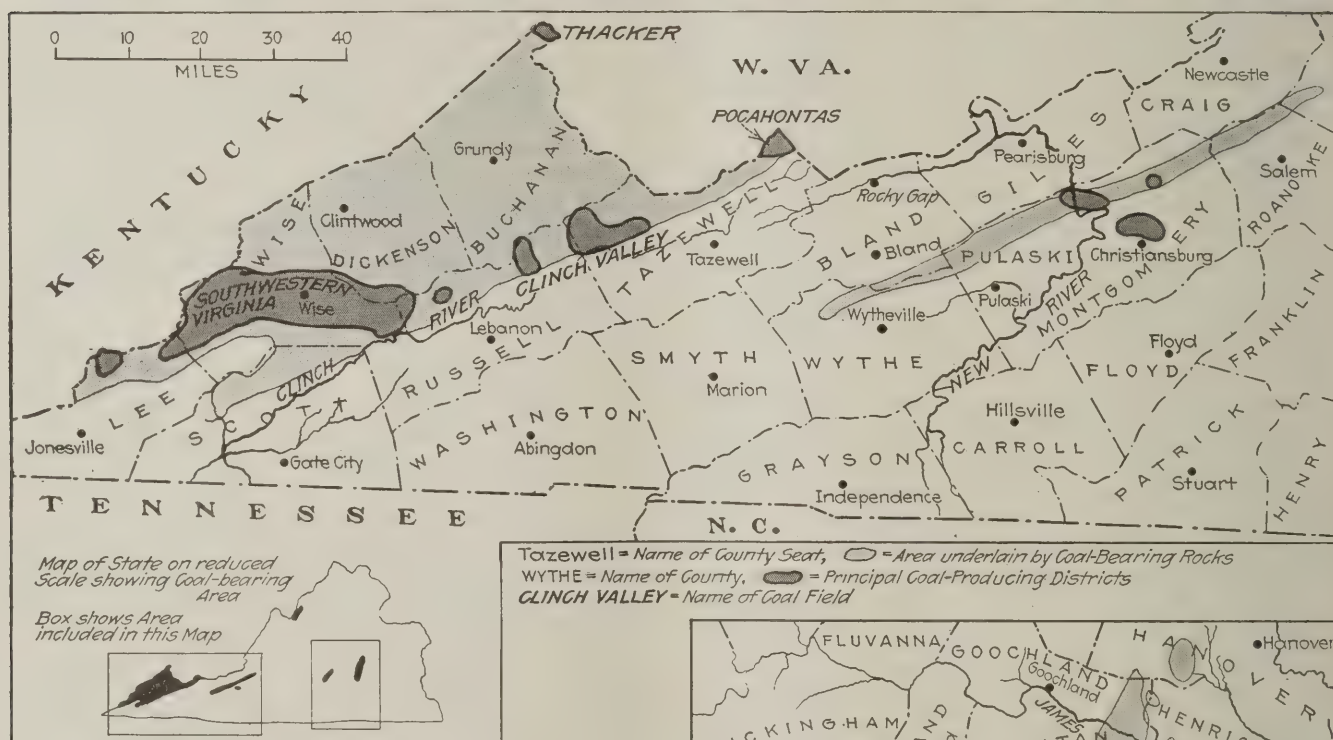

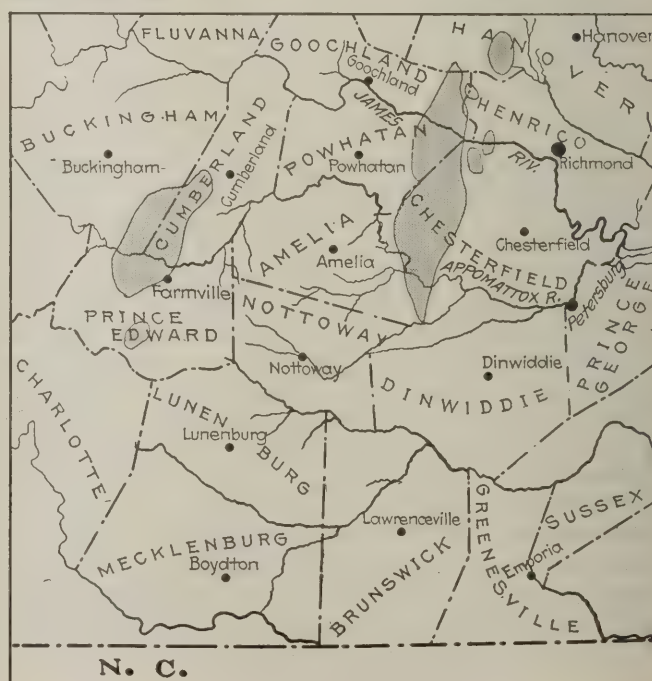

Fig. 1—Maps of Two Coal Fields of Virginia, the Eastern and the Central

The map of the Eastern area prepared some years ago by the U. S. Geological Survey, before the Valley coal beds had been given a close examination shows in a generalized way the areas they occupy. As will be seen in Figs. 2 and 3, greater detail is now at hand. The maps with the key sketch above this title exhibit somewhat completely the coal-bearing areas of the State of Virginia. In 1922 Wise County produced 5,022,866 tons; Russell County, 2,070,574 tons; Tazewell County, 1,563,847 tons; Dickenson County, 870,234 tons; Lee County, 762,305 tons; Montgomery, 42,194 tons. All the rest together—there are no separate returns available—totaled 106,281 tons. The price of the Montgomery coal, \$4.34 per net ton, led that of all other listed counties. Wise County coal sold for \$2.43; Russell coal, for \$2.51; Dickenson, for \$2.59; Lee, for \$2.68, and Tazewell for \$2.90. The price in the other counties averaged \$4.09 and the whole state railroad product \$2.57. This is evidence that certain at least of the Valley coals have a high market value.

face of Tract Mountain. The point at which the outcrop makes this sharp bend is arbitrarily taken as the western end of the Brushy Mountain field, and the area that lies east of this point is here called the Pulaski field, because the outcrop at its other extremity passes through the town of Pulaski.

Little mining has been done in the Pulaski field and few prospects can be found. The Merrimac bed is reported to be 12 or 15 ft. thick in an old mine two miles north of Pulaski, but the report could not be verified. Only one small mine is now operating in this field on the Merrimac coal bed. This mine is just south of Pulaski and is operated by the High Carbon Coal Co. The coal bed in this mine has a thickness of 7 ft., including the customary bony partings.

Wythe County.—There are two separate and distinct coal fields in Wythe County—one in the vicinity of Max Meadows, which will be called the Max Meadows coal field, and the other along the south slope of Brushy or Little Walker Mountain (C), on the headwaters of Reed Creek, which will be called the Reed Creek coal field (F).

The Max Meadows field is different from any of the fields so far described, as it consists of a rather flat synclinal trough six miles in length, extending from Gunton Park or Clark Summit on the east to the west fork of Miller Creek, about 2½ miles northwest of Max Meadows. A sketch map of this field is given in Fig. 2.

Only a little mining or prospecting has been done in this field, and consequently but little is known of the

coal beds except those in the vicinity of Gunton Park, where a mine recently was opened about a mile west of the railroad by the Pulaski Smokeless Coal Co. (12). The coal bed in which mining is now carried on apparently is the highest workable bed in the formation and is therefore called locally bed No. 1. This bed, where sampled by the geologists, is 5½ to 6½ ft. thick and has several partings. It dips only about 25 deg. to the south, but this dip is not uniform, as several rolls and irregularities of dip are shown in the mine slope.

COAL BADLY CRUSHED AND PROBABLY BUNCHED

Recently a tunnel was driven through the rock floor a distance of 12 ft. to a large but considerably crushed and distorted coal bed, which apparently is more than 20 ft. thick and carries 15 or 16 ft. of coal. The measurements given here, however, are not reliable, as the entry cut the coal bed in a roll and the coal as well as the partings in the bed are much disturbed and possibly bunched, so that probably the bed appears to be thicker than it really is. This bed is called No. 2. In addition to beds Nos. 1 and 2, there is another bed which, according to apparently reliable witnesses, lies not more than 20 ft. below bed No. 2 and contains at least 4 ft. of clean coal. This bed is known as No. 3.

A bed that seems to be bed No. 1 was prospected several years ago near the railroad, and beds of this group also were prospected about 1½ miles west of the mine of the Smokeless Coal Co. Probably the most satisfactory prospecting on these beds has been done

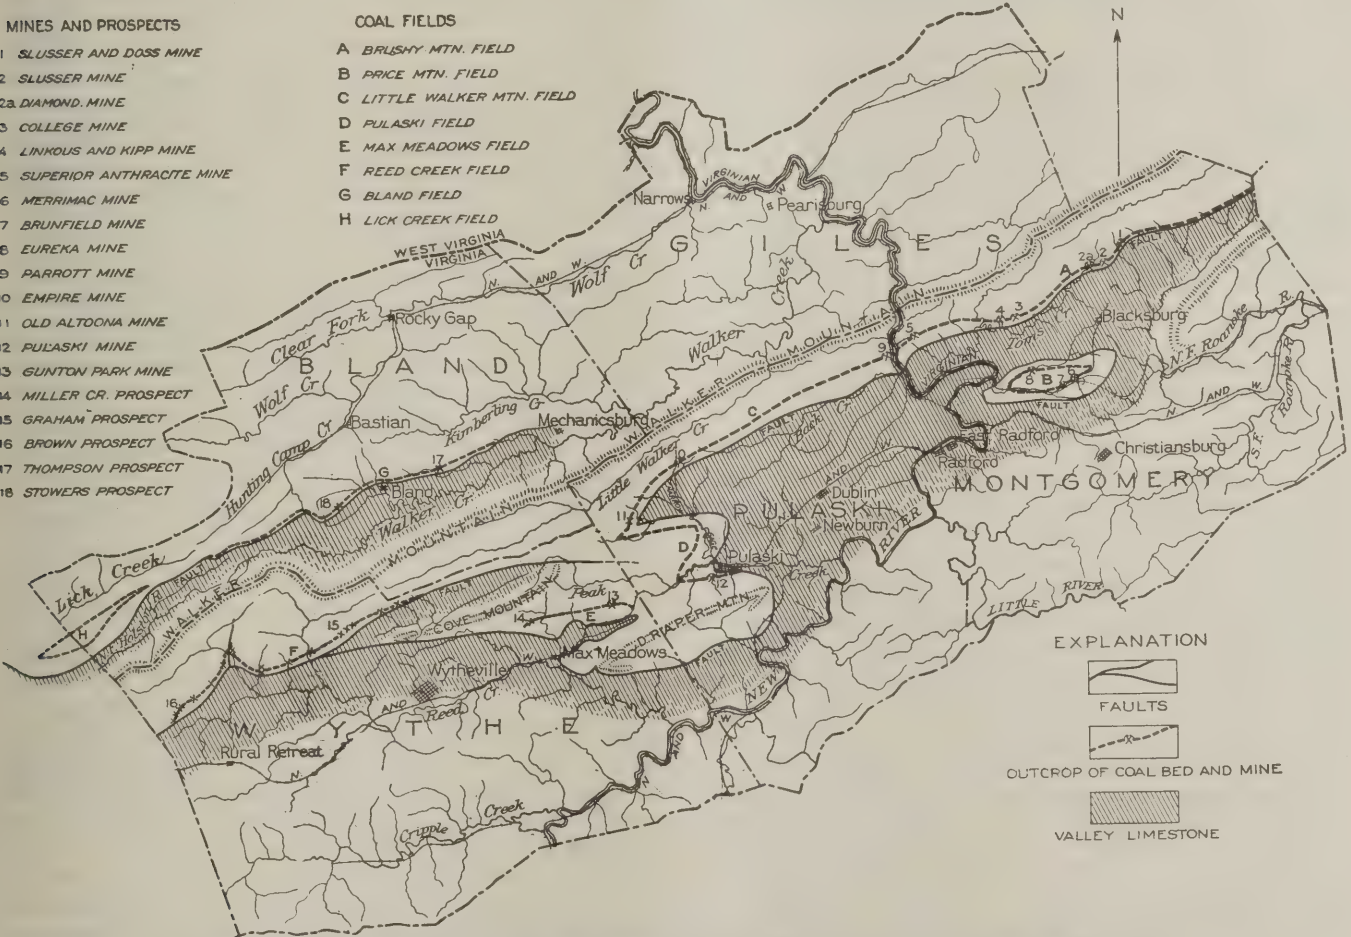

Fig. 2—Valley Coal Fields in Montgomery, Pulaski, Wythe and Bland Counties, Virginia

From the west corner of Bland County, near Lick Creek, to the most easterly corner of Montgomery County is 7½ miles. The area of the fields probably is large but the steepness of the dip soon carries the coal

to such profound depths as to make the coal unworkable, and its badly crushed condition makes the operation of some of it of questionable advantage. Other areas are extremely high in ash, and in fact in

all areas excessive ash is found. However, each operating area must be considered in detail and as yet none too much is known of the possibility of removing ash by washing, flotation and tabling.

Fig. 3—Max Meadows Coal Field with Section Showing Form of Syncline

This area is noteworthy for its overturned measures, which will make mining difficult. The depth of the coal at the deepest point probably is not greatly in excess of 1,000 ft. and it is doubtless nearly flat over a large area at the bottom of the basin. Apparently there is no coal under the Valley limestone, which, as in Fig. 1, is hatched to delimit its area.

on the west fork of Miller Creek northwest of Max Meadows.

At this place a 40-ft. shaft shows that bed No. 3 ranges in thickness from 3 to 10 ft., the greater thickness probably being due to movement within the coal. Bed No. 2 is exposed 20 ft. above bed No. 3, but could not be measured because the timbers in the shaft concealed it. Good coal 5 ft. thick is found in a near-by opening, and the bed in the shaft appears to be at least 7 ft. thick. Bed No. 1 lies 15 or 20 ft. above No. 2. On the outcrop bed No. 1 ranges in thickness from 6 to 5 ft., but it contains many bony partings.

COAL BEDS APPEAR TO END NEAR MAX MEADOWS

The westward extent of these coal beds is not definitely known by prospectors. The opinion is commonly held that the beds continue westward as far as Cove Creek, where they are overlapped and concealed by the Valley limestone, but this is improbable, for a few hundred feet west of the prospect shaft the outcrop of a sandstone can be traced underlying the coal until it assumes a position almost at right angles to the general strike of the coal beds.

This feature shows clearly that the coal beds end here in a synclinal point, and their outcrop, if it could be traced, would turn back to the east in the overturned south limb of the syncline and connect with the prospect on Miller Creek, half a mile below the forks of the creek.

The geologic structure of the northern part of the syncline is simple, as is shown by the regularity of the outcrop of the coal beds from one end of the basin to the other and by the regularity of the band of red shale (Maccrady formation) that occupies the middle of the trough. A rough measurement of the thickness of the

rocks that lie between the uppermost coal bed and the Maccrady shale south of the mine of the Smokeless Coal Co. is about 1,000 ft. The belt of red shale can be clearly seen from the forks of Miller Creek downstream for a distance of about 1,500 ft. and on the direct road leading from Gunton Park station to the coal mine.

As the Maccrady shale is the highest formation in this trough, its outcrop must mark approximately the middle of the trough, and hence the deepest part. If the coal lies 1,000 ft. below this red shale, it probably is at about that depth below the surface, and as the red shale here dips only about 10 deg., the coal bed directly beneath must lie nearly flat. These features afford a means of making an estimate of the area of available coal, for the trough is about six miles long, and the coal probably is workable for about a mile back of the outcrop.

BEDS VERTICAL AND PERHAPS OVERTURNED

From the southernmost boundary of the red shale southward the rocks are much disturbed, and where they are well exposed they dip steeply to the south or stand in a vertical position. This relation indicates clearly that the south limb of the trough is either sharply upturned or completely overturned, as can be seen on Miller Creek. If this condition prevails it does not look promising for the mining of coal in the south limb of the syncline.

The cross-section on Fig. 3 shows that the coal-bearing rocks on Miller Creek lie in a syncline whose southern limb is sharply overturned. Devonian rocks are exposed beneath the Price formation in Brushy Mountain, on the north edge of the field, and the same rocks, though much crushed and distorted, are exposed

also at the entrance of the gorge of Miller Creek, about a mile north of the railroad at Max Meadows. At both places these rocks dip to the south, but in the outcrop nearer the town they are overturned, as shown on Fig. 3.

Reed Creek Field.—The Reed Creek field (F) includes a rather narrow belt of outcrop of the Price sandstone along the south slope of a ridge known as Little Walker Mountain or Brushy Mountain. Because this field lies on the flank of the same ridge that carries coal in Montgomery and Pulaski counties many think that it is the westward extension of the Little Walker Mountain field (C).

The Little Walker Mountain field of Pulaski County ends in a synclinal point near the old Altoona coal mine, and the conglomerate that forms the lowermost bed of the Price formation has been traced definitely to an end on Little Walker Mountain, near the head of Crockett Cove. The Price formation comes in again near the Wytheville-Bland road, probably by the westward plunge of the synclinal axis, and there is a distinct interval in Crockett Cove, on Little Walker Mountain, in which there are no Carboniferous rocks.

Although the Price formation is exposed in Crockett Cove east of the Bland road, no signs of coal appear nearer than a point about a mile west of this road. Here the coal has been opened on the head of Goose Creek within 100 ft. of the edge of the limestone, which, as shown in Fig. 2, is faulted against and upon it.

BED 13 FT. THICK AND PITCHING 45 DEG.

From the prospect noted above the outcrop can be followed westward by means of old prospects in almost every ravine, but the coal is exposed at only a few places. Recent work done on a prospect belonging to Dr. John P. Graham, northwest of Queens Knob, where the coal bed dips 45 deg. south, has produced a considerable stockpile, and an analysis of a selected sample of this coal is given in the article entitled "Can the Valley Coal Fields of Virginia Compete with Those of the Anthracite Region?" which appeared in last week's issue of *Coal Age*, but the percentage of ash in this analysis probably is much less than it would be in a sample representing the entire bed. Doctor Graham reports that at the lowest point attained in the prospect the coal bed has a thickness of 13 ft., between well-defined walls. Unfortunately the prospect is caved, and the coal bed can no longer be seen.

West of Reed Creek the old prospects are in bad condition, and at only one locality, near the western extremity of the outcrop, was it possible to see the coal in place. At the C. C. Brown prospect, near the head of Mudlick Creek, a measurement shows that the coal bed becomes thinner toward the west, and a sample of coal obtained at this place indicates that it is of poorer quality than that to the east.

At the head of Mudlick Creek the outcrop of the coal bed swings to the south and is cut off or concealed by the fault. No coal is reported from places west of this locality, though the lower part of the Price formation outcrops nearly as far west as Bear Branch, 5 miles east of Marion.

In this field the movement thus produced within the coal bed has ground much of the coal nearly to powder and crowded some of it into great masses or squeezed it out altogether.

Bland County Field.—The coal beds of Bland County crop out in a narrow belt on the south slope of Brushy

Mountain. The coal beds continue southwestward into Smyth County.

In the Bland field the coal crops out at many places, but the coal beds seem to be thin and to have many partings. Two samples that were analyzed contained nearly 50 per cent of ash, and therefore they cannot be considered a source of fuel either now or for a long time to come.

Other Fields.—Coal beds of the same geologic age as those just described are found in other counties of Virginia, but most of them are so thin and so poor in quality that they are at present valueless.

Carnegie Institute Will Investigate Coal-Mining Problems

Studies of certain practical details of coal-mining practice will be conducted by six fellows to be appointed by the Carnegie Institute of Technology, Schenley Park, Pittsburgh, Pa. They are part of the co-operative mining courses of that institution in which the Pittsburgh Experiment Station of the U. S. Bureau of Mines and an advisory board of mine operators and engineers collaborate. The fellowships, which carry an emolument of \$750 a year of ten months' duration, are open to the graduates of colleges, universities and technical schools who are properly qualified to undertake research investigations.

Four of the fellowships are financed by the Carnegie Institute of Technology and two by coal-mining companies of western Pennsylvania. The following subjects have been suggested for investigation:

(1) GEOLOGY—(a) Correlation of coal seams by microscopic characteristics; (b) Colloid chemistry and the constitution of coal; (c) Microscopic study of the coking constituents of coal.

(2) ACID MINE WATERS—(a) Selection and performance of equipment for handling such water; (b) Action of such water on concrete and protective linings; (c) Analytic test for corrosion.

(3) COAL MINING—(a) Efficiency on blasting coal; (b) Possible substitutes for wood in mine timbering; (c) Friction losses and efficiency in mine ventilation.

(4) COAL WASHING—(a) Wet and dry methods; (b) Utilization and disposal of washery waste.

(5) UTILIZATION OF COAL—(a) Smelting qualities of coal; (b) Determination of comparative rate of carbonization of gas coals; (c) Combustion of low-volatile bituminous coal in house-heating furnaces.

(6) SAFETY AND EFFICIENCY—(a) Electric trailing cables used on portable motors and reel locomotives; (b) Carbon-monoxide indicators and their adaptability for mining and metallurgical uses; (c) Efficiency of dust-collecting instruments; (d) Rock dusting; (e) Humidification of mine air.

(7) COAL STORAGE—(a) Laboratory tests of relative tendency of coals to fire spontaneously; (b) Effects of size on deterioration in storage; (c) Maximum safe storage temperature.

(8) MINE EXPLOSIONS—(a) Modification of Stoke's law for settling of coal dust; (b) Time-pressure relations in dust explosions; (c) Conductivity and specific heat of coal; (d) Static charges in coal mines; (e) Effect of electric field in propagation of explosions.

The fellowships will begin Aug. 18, and applications must be made prior to May 15.

Is Your Tax Bill Too Heavy?

Your Taxes May Be Much Reduced if Higher Than Those of Companies Having Like Earnings

A Heavy Tax on Low Production May Put a Coal Operator at Great Disadvantage—The Unfair Impost May Be Due to Excessively Large Loans, Low Valuation of Property or Other Abnormal Conditions

BY GEORGE C. WILLIAMS*
Tax Consultant, New York City

MANY coal-mining companies have greatly overpaid their federal profits taxes in 1917 and subsequent years through lack of knowledge of the special relief provisions of the various revenue acts. As a result these companies are placed at a serious disadvantage in competing with representative concerns.

In support of the contention that such undue payments have been made tax data on a few coal companies have been listed in Table I, the figures being drawn from the 1917 statistics on coal-mining companies as prepared by the Bureau of Internal Revenue and found in Senate Document No. 259, Corporate Earnings and Government Revenues, Pages 130-133, inclusive. This table not only indicates the gross disproportion between the profits taxes paid by representative coal companies but also the fact that unless the concerns paying the higher rates of profits tax are granted relief under the special relief provisions exceptional hardships will be imposed.

Where a company was organized many years ago and bought its coal at a low price it will find the tax as ordinarily calculated far higher than would be paid by a company which bought its lands at a later date, because its valuation will be far less. Only the special relief provisions can rectify that abnormal taxation.

Company No. 17? (3) Is there any way under the tax laws that Companies No. 2 and No. 18 can obtain relief from their excessive taxes?

Some of the reasons why Companies No. 2 and No. 18 pay excessive taxes and the means by which they can obtain relief from this exceptional hardship will be discussed in detail in the following paragraphs.

Briefly, a domestic concern, in order to be entitled to relief under these special provisions, must prove either: (1) That its invested capital cannot be determined; or, (2) That its profits tax, if determined without the benefit of the relief sections, would, owing to "abnormal conditions" affecting its capital or income, work upon it an exceptional hardship by reason of having to pay a profits tax that is in excess of the average profits

tax paid by normal representative concerns.

The average profits tax is determined by comparison with representative concerns. The following example outlines in a general way the method of arriving at the average tax.

Assume Company A has a net income of \$100,000 and pays a profits tax under Section 326 of \$65,000. Abnormal conditions have been proved under Section 327. Companies B, C, D, E and F each have an average net income of \$100,000 and an average tax of \$40,000—ratio 40 per cent. The tax of Company A under Section 328 would be 40 per cent of its net income, which is \$40,000.

Special relief may be obtained for the taxable year 1917 under the provisions of Section 210 of the Revenue Act of Oct. 3, 1917, and for the taxable years 1918-1921, inclusive, under the provisions of Sections 327 and 328 of the Revenue Acts of 1918 and 1921. The special relief provisions are alike in the different revenue acts except for slight differences which are not material in the coal-mining industry. Sections 327 and 328 of the Revenue Act of 1921 read as follows:

Sec. 327. That in the following cases the tax shall be determined as provided in Sec. 328: (a) Where the Commissioner is unable to determine the invested capital in Sec. 326; (b) In the case of a foreign corporation or of a corporation entitled to the benefits of Sec. 262; (c) Where a mixed aggregate of tangible property and intangible property has been paid in for stock or for stock and bonds and the Commissioner is unable satisfactorily to determine the respective values of the several classes of property at the time of payment, or to distinguish the classes of property paid in for stock and for bonds, respectively;

TABLE I—TAXES PAID 1917 BY TWENTY SELECTED COAL MINING COMPANIES

No.	Code No.	Net Income	Total Tax	Total Tax to Net Income, Per Cent
1	38	\$35,751	\$5,122	14.33
2	142	35,978	20,545	57.10
3	190	50,449	8,038	15.93
4	6	50,900	27,870	54.75
5	97	78,835	14,250	18.08
6	267	79,657	46,382	58.23
7	72	86,710	20,746	23.93
8	208	84,944	50,436	59.38
9	107	107,676	17,851	16.58
10	219	104,109	59,657	57.30
11	77	171,553	40,360	23.53
12	19	177,395	106,795	60.20
13	214	288,789	72,245	25.02
14	232	271,944	154,243	56.71
15	67	377,762	128,072	33.90
16	253	360,328	198,953	55.21
17	36	526,778	128,849	24.46
18	250	541,722	301,592	55.67
19	62	666,220	211,550	31.75
20	157	612,358	311,370	50.83

In analyzing the foregoing table many questions arise, among which are: (1) Why does Company No. 2 pay four times the tax paid by Company No. 1 on a similar income? (2) Why should Company No. 18 pay over one hundred fifty thousand dollars more than

*Formerly assistant chief of special assessment section, Natural Resources Division of the Internal Revenue Bureau.

(d) Where upon application by the corporation the Commissioner finds and so declares of record that the tax if determined without benefit of this section would, owing to abnormal conditions affecting the capital or income of the corporation, work upon the corporation an exceptional hardship evidenced by gross disproportion between the tax computed without benefit of this section and the tax computed by reference to the representative corporations specified in Sec. 328. This subdivision shall not apply to any case (1) in which the tax (computed without benefit of this section) is high merely because the corporation earned within the taxable year a high rate of profit upon a normal invested capital, nor (2) in which 50 per centum or more of the gross income of the corporation for the taxable year (computed under Sec. 233 of Title II) consists of gains, profits, commissions, or other income, derived on a cost-plus basis from a government contract or contracts made between April 6, 1917, and Nov. 11, 1918, both dates inclusive.

Sec. 328. (a) That in the cases specified in Sec. 327 the tax shall be the amount which bears the same ratio to the net income of the taxpayer (in excess of the specific exemption of \$3,000) for the taxable year as the average tax of representative corporations engaged in a like or similar trade or business bears to their average net income (in excess of the specific exemption of \$3,000) for such year. In the case of a foreign corporation or of a corporation entitled to the benefits of Sec. 262 the tax shall be computed without deducting the specific exemption of \$3,000 either for the taxpayer or the representative corporations.

In computing the tax under this section the Commissioner shall compare the taxpayer only with representative corporations whose invested capital can be satisfactorily determined under Sec. 326 and which are, as nearly as may be, similarly circumstanced with respect to gross income, net income, profits per unit of business transacted and capital employed, the amount and rate of war profits or excess profits, and all other relevant facts and circumstances.

(b) For the purposes of subdivision (a) the ratios between the average tax and the average net income of representative corporations shall be determined by the Commissioner in accordance with regulation prescribed by him with the approval of the Secretary.

(c) The Commissioner shall keep a record of all cases in which the tax is determined in the manner prescribed in subdivision (a), containing the name and address of each taxpayer, the business in which engaged, the amount of invested capital and net income shown by the return, and the amount of invested capital as determined under such subdivision. The Commissioner shall furnish a copy of such record and other detailed information with respect to such cases when required by resolution of either House of Congress, without regard to the restrictions contained in Sec. 257.

Under Sec. 210 of the Revenue Act of 1917 and Sec. 327(a) of the Revenue Acts of 1918 and 1921 a concern's profits tax liability should be determined under the provisions of said sections where the statutory invested capital cannot be determined. This condition may arise where through defective accounting or lack of adequate data the statutory invested capital cannot be determined.

Under Sec. 327(d) a large number of coal-mining corporations are entitled to special relief. In order to obtain relief under this provision a corporation's profits tax liability must (1) be in excess of the average profits tax paid by representative corporations similarly circumstanced; (2) impose an exceptional hardship on the corporation by reason of its having to pay a profits tax that is in excess of the average profits tax paid by representative concerns; and (3) be

excessive due to the existence of abnormal conditions.

(1) It is obvious that to obtain relief under the special assessment provisions a corporation's profits tax liability must be in excess of the profits tax paid by representative concerns. As a general rule if a corporation's profits tax is excessive it is not a difficult matter to determine the abnormalities causing the excessive tax, and to obtain special relief.

It is not essential to submit with the application for special relief data showing the average profits tax of representative concerns. Such data if available, however, will give the taxpayer some idea as to whether his tax is excessive and also aid the Income Tax Unit in arriving at the average tax.

In order to determine whether a concern's profits tax liability is in excess of the average tax of representative concerns, an analysis should be made of available statistics of representative competing concerns. Each case must be considered separately and no general rules can be laid down. The following example illustrates one of the many ways of determining an excessive profits tax rate:

Assume that Company A has an annual output of 100,000 tons of coal and has 500,000 tons of coal reserves. The cost value of the coal reserves at \$1 per ton would give Company A an invested capital of \$500,000.

Companies B, C, D and E, representative competitors of A, also mine an average of 100,000 tons a year, but they have average coal reserves of 2,000,000 tons that cost \$2,000,000. The cost value of the coal reserves would give B, C, D and E an average invested capital of \$2,000,000.

It is apparent that A's competitors obtain the benefit of a larger capitalization and as a result pay a much lower profits tax, for the reason that a larger invested capital results in a lower profits tax.

(2) The profits tax as determined under Sec. 326 must impose an exceptional hardship. The term "exceptional hardship" as used in Sec. 327(d) means the hardship of inequality evidenced by gross disproportion between the tax computed without the benefit of Sec. 327 and 328 and the tax computed by reference to representative concerns specified in Sec. 328, but inequality alone is not sufficient to grant relief under Sec. 328, the inequality must be due to abnormal conditions affecting capital or income.

A gross disproportion and exceptional hardship may exist where a concern's profits tax liability on a net income of \$100,000 is \$40,000 and where the average tax paid by representative concerns on \$100,000 incomes is \$35,000. The terms "gross disproportion" and "exceptional hardship" do not mean that in order to obtain relief a corporation's tax liability must be double the average tax of representative concerns.

(3) The exceptional hardship caused by an excessive profits tax must be due to the existence of "abnormal conditions" affecting the net income or capital of a corporation. The amount of relief obtained under the special relief provisions depends largely on discovering the abnormal conditions peculiar to each case and citing decisions of the Income Tax Unit in support thereof.

The phrase "abnormal conditions affecting the capital or income of a corporation" has been defined by the

Wherever a company has borrowed much money or rents plant and equipment its taxes under the revenue acts will be excessive, except as modified by the special relief provisions which enable it to pay taxes proportional to those "of representative corporations engaged in a like or similar trade or business."

Income Tax Unit to include the following cases, among others:

(a) Where a corporation is placed in a position of inequality because of the time, or manner of organization. An illustration, of one of the numerous abnormal conditions coming within the scope of this definition, is as follows:

Company A was organized in 1905 and acquired coal lands containing 2,000,000 tons of coal at \$1 per ton. On Jan. 1, 1918, there remained 1,000,000 tons of coal and A's invested capital was \$1,000,000.

Companies B, C and D acquire similar coal lands on Dec. 31, 1917, containing an average of 1,000,000 tons of coal at \$2 per ton. The average invested capital of B, C and D is \$2,000,000.

A, B, C and D each mine 100,000 tons of coal and each makes a profit of \$100,000. A's tax would be excessive compared with B, C and D for the reason that A would only be allowed \$1,000,000 invested capital, and B, C and D an average invested capital of \$2,000,000 on similar net incomes.

Company A would be entitled to relief for the reason that it is placed in a position of inequality because of the *time* of organization. In this example A would also have an abnormal condition affecting net income for the reason that B, C and D would be allowed a depletion rate based on Dec. 31, 1917, values, whereas A, at best, could obtain only a depletion rate based on March 1, 1913, values. No recognition is given to the fact that under the statutory provisions of the law, A had capital unproductively invested in the 1,000,000 tons of coal since 1905. The only way these inequalities can be removed is under the special relief provisions.

(b) Where the capital employed, although a material income-producing factor, is small, or a large part borrowed. One of the many examples of this abnormal condition in the coal mining industry is as follows:

A operating a mine valued at \$1,000,000, composed of coal reserves valued at \$800,000 and a plant valued at \$200,000. A rents the plant and pays a nominal rental. The coal reserves were acquired by the payment of \$100,000 cash and a mortgage of \$700,000. A's statutory invested capital would be \$100,000 and he would be entitled to relief under the provisions of Sec. 327(d) for the reason that the capital employed, although a material income-producing factor, was in a large part borrowed. An exceptional hardship would be imposed because similar representative concerns that had no borrowed money would be allowed \$800,000 for statutory capital purposes. The rental payment in this case is analogous to an interest payment and the renting of plant or equipment results in the same abnormal condition as the use of borrowed money.

(c) Where intangible assets of recognized value and substantial in amount, built up or developed by the taxpayer are excluded from the invested capital computed under Sec. 326. This definition would include patents, trade names, good will, etc., developed by the taxpayer.

(d) Where the net income for the year is abnor-

mally high, due to the realization in one year of income earned during a period of years.

This condition may arise where the taxable net income of a corporation is the fruit of activities antedating the taxable year, or where the taxable net income is to some extent the result of capital unproductively invested in prior years. This abnormality, to a large extent, is the cause of many coal-mining companies paying an excessive tax for the reason that "carrying charges" are charged directly to operations. This also is one of the reasons why the coal-mining industry as a whole pays about the highest profits-tax rates of the numerous industries in the United States under the Federal Profits Tax Laws.

"Carrying charges" are capital expenditures made in prior years that benefit future years. Such charges accrue where assets, such as coal reserves, are carried

upon which no profit will be realized until some future date. A few "carrying charges" in the coal-mining industry may be mentioned to illustrate the principles that distinguish them:

(1) Interest on money borrowed to carry coal reserves upon which no profit will be realized until some future date;

(2) An estimated interest charge on the "owned capital," i.e., capital stock and surplus that is invested in assets upon which no profit will be realized until some future date;

(3) Development expenses.

Where a mineral deposit has a life of twenty years, nineteen-twentieths of the first year's "carrying charges" should be capitalized and amortized on a unit basis to the unmined reserves. As the federal tax laws do not take cognizance of this fact under the statutory provisions of the law, the only source of relief is under the special relief provisions, the abnormal condition in this case being caused by the taxable net income being the result of capital unproductively employed in prior years and the fruits of activities antedating the taxable year. A concrete example of "carrying charges" is as follows:

A buys with borrowed money a coal deposit containing 200,000 tons of coal for \$100,000. The interest charge is 8 per cent per annum on the borrowed money. The deposit has a life of two years, 100,000 tons being sold the first year for \$200,000 and 100,000 tons in the second year for \$200,000. Assume for the sake of simplicity that the interest charges are the only expenditures.

At the end of the first year A liquidates all the borrowed money, and charges to the first year's profits the entire 8 per cent interest payment. The following erroneous yearly statement of profits results:

	First Year	Second Year
Income.....	\$200,000	\$200,000
Depletion.....	50,000	50,000
Total.....	\$150,000	\$150,000
Interest.....	8,000	None
Net Income.....	\$142,000	\$150,000

It can be seen from an analysis of this illustration that the first year's income is understated and the second year's overstated, for the reason that the \$8,000 interest charge is a "carrying charge" to the extent

If a coal-mining company or coal brokerage firm believes that its federal profit taxes have been overpaid and are excessive, application should be made for consideration under the special relief provisions. Great care should be taken that the reasons why special relief is necessary are cited in detail together with the facts upon which such reasons are based. Where the tax has been assessed and paid a claim for refund should be filed as soon as possible to prevent the tolling of the statute of limitations.

of \$4,000 which should have been capitalized in the first year and charged as an expense in the second year. Where a corporation's taxable year is analogous to the second year in the above example the net income may be said to be the result of capital unproductively invested in prior years. A corporation that has mined in a taxable year coal that has been carried for a period of years is placed at a serious disadvantage with a concern that mines from a coal deposit with a comparatively short life.

(e) Where a corporation's war-profits credit due to an abnormal pre-war period is less than the war profits credit allowed representative concerns with normal pre-war periods.

(f) Where a corporation has paid no salaries to its officers or has paid them salaries which were unusually low in comparison with the salaries paid to officers of representative concerns. It must be proven, however, that the officers for whom it is claimed were entitled to

a salary for actually rendered services and were not merely "figureheads."

(g) Where a corporation's net income is abnormally high due to the realization of profits on the sale of capital assets. An example of this abnormality is where a corporation liquidates all or part of its business.

(h) Where proper recognition or allowance cannot be made for amortization, obsolescence or exceptional depletion due to the World War. In connection with amortization allowances the Income Tax Unit has recently held in A.R.R. 3920, Bulletin 11-29-1146 that, "Coal used in the manufacture of war materials is an article which contributed to the war."

It would therefore follow that coal-mining companies were entitled to amortization of war facilities, and that where proper recognition or allowance cannot be made for amortization, obsolescence or exceptional depletion, consideration should be granted under the special relief provisions.

Pennsylvania Coals Suited to Baking, but Need Is Not Obvious

STUDIES of low-temperature carbonization of the Pittsburgh and Upper Kittanning coals, made at the Pittsburgh Experiment Station, by the U. S. Bureau of Mines in co-operation with the Carnegie Institute of Technology indicate that the Pittsburgh bed of coal is in general well suited to that process. When carbonized at 550 deg. C. in a stationary vertical retort it will yield per ton 33 to 35 gallons of tar, 3,500 cu.ft. of 600-B.t.u. gas, 1,400 lb. of coke having 10-per cent of volatile matter, and 6 to 8 lb. of ammonium sulphate.

The other parts of the Pittsburgh bed—namely, the rooster, the lower roof and the upper roof are of similar coking quality, differing only in the quantity of by-products yielded. These decrease in the order given. The yield of tar from the upper roof is only 66 per cent of that from the regular seam, and from the rooster coal 75 per cent. The difference is largely due to the variation in the ash content of the different sections, and not to the chemical composition of the coals.

TAR YIELD OF SEMI-BITUMINOUS COAL LOW

The Upper Kittanning coal tested was not a good low-temperature coking coal. The coke was not dense, and the yield of by products was low. The particular coal coked was a semi-bituminous coal with low volatile matter and was not expected to yield much tar.

The total quantity of crude light oil suitable for motor fuel that was obtained directly from Pittsburgh or Freeport coal by distillation at 550 deg. C., and by cracking is approximately 7.1 gallons per ton, or 2.6 per cent by weight of the coal. The net refined motor fuel from the process is 4.6 gallons per ton, or 1.7 per cent by weight of the coal.

Superheated steam has an effect upon the byproducts of low-temperature carbonization. The tars obtained by its use were more viscous and contained a smaller quantity of light oils and a larger quantity of heavy oils. The quantity of byproducts obtained by carbonizing with superheated steam was practically the same as without steam. To some extent the steam prevented secondary decomposition.

Research on the low-temperature carbonization of coal has been in progress for a number of years, the main object being to produce a coke more suitable for

domestic use than the high-temperature product of the gas works and coke ovens, and at the same time to effect a higher recovery of constituents in the tar oils, according to J. D. Davis, fuels chemist, Bureau of Mines, and V. Frank Parry, research fellow, Carnegie Institute of Technology, in Bulletin 8, Coal Mining Investigations, just published by the Carnegie Institute of Technology, Pittsburgh, Pa.

Much valuable data has been accumulated, but this in the United States has not as yet led to any industrial development worth mentioning. Since the World War, investigators have been particularly active in England, where one of the main incentives is the production of fuel oil which that country would like to obtain from a domestic source. Presumably, there is also a good demand for low-temperature coke for open fires in English homes.

DEMAND SMALL FOR LOW-TEMPERATURE PRODUCTS

In Germany, during the war, research on low-temperature tar oils was carried on intensively on account of the demand for lubricants which would substitute for mineral oils. Such lubricants can be made from refined tars, and quantities of lubricants were made from that source during that period, but it is doubtful whether they are competing now with imported petroleum oils. Obviously, a definite demand must exist for low-temperature products before any extensive development of the method can be expected. The abundant supply of petroleum in the United States and a like supply of coal suitable for high-temperature coking would seem at least for a time to preclude competition of low temperature products in either field.

There is, however, a strong possibility of better utilization of waste coals and coals of inferior rank by low-temperature methods, and this phase of the subject should be a fruitful field for research. Further, the utilization of low-temperature tar oils for special purposes, as for example, for the preservation of timber, is a reasonable expectation; as is also the improvement of high-temperature coke by preliminary low-temperature treatment. These points have yet to be proved industrially practicable.

Bulletin 8, "The Low-Temperature Carbonization of Pennsylvania Coals—the Pittsburgh and Upper Kittanning Beds," may be obtained from the Carnegie Institute of Technology, Pittsburgh, Pa., at a price of 40c.

Institute of Mining and Metallurgical Engineers Take Stock of Progress

Year Has Seen Great Development in Conveyor Mining, Flotation of Coal in Quicksand and Dry Cleaning of Coal—New Light on Rock Dusting—Foreign Lights Illuminate Domestic Problems.

With only a few coal-mining company officials present to discuss the able papers presented and read, the American Institute of Mining and Metallurgical Engineers held at the Engineers' Societies Building, New York City many eventful sessions during its 129th meeting, Feb. 18-21. Several sections were continually in progress and plenty of entertainment was provided to fill the evenings, recesses and the final day.

The first evening was enlivened by a smoker with radio and slide hits at the institute's officers. Only with difficulty could the crowd be accommodated. The radio proved its ability to give vent to mysterious raucous sounds, finally announcing that President Mathewson was needed in the cloak room as his stored apparel was leaking. A clever trickster discovered a hare down Secretary Sharpless' back, and explained the art of jugglery most satisfactorily, only to mystify the crowd by performing the feat in an entirely different and inexplicable way. A film explaining radio and one portraying a fierce and combative mouse were other features. Harlowe Hardinge exhibited the music obtainable by bending a common hand-saw and stroking its edge with a fiddle bow. If you think this an easy trick, just try it before you make up your mind.

MEMBERS IN CANADIAN MOVIES

On the evening of Tuesday, motion pictures taken by the Ontario government of the trip of the institute through Toronto and the mining regions of that province were presented, several of the members recognizing themselves and their friends on the shining sheet. The films have been presented to the institute by the Ontario government. Lantern slides and motion pictures exhibited also an eventful fishing trip in Canada and two men undertaking, at different times, to ride on a moose as that animal swam in one of the lakes of the North Country. Neither ride was long, nor was the ending of it graceful, but the narrator's story and the pursuit in a canoe as portrayed on the screen was worth traveling a long way to hear and see. A snow-packing roller with wheels built like big screws showed how it is proposed to "mush" in northern latitudes where the removal of the snow is not possible. A buffet lunch and a dance concluded the evening's entertainment.

Wednesday evening ushered in the annual dinner in the Waldorf-Astoria with J. V. W. Reynnders as toastmaster and E. P. Mathewson, the retiring president; William Kelly, the new president and Dr. R. V. Wheeler, Director

of the British Safety-in-Mines Station, as speakers. The James Douglas medal was presented to C. W. Merrill as recognition of his work in cyanidation and other forms of metallurgical practice.

On Tuesday morning the annual business session was held in the auditorium. The report of the secretary showed a shrinkage in membership of 285, reducing the roll from 9,413 to 9,128. The gross loss of membership was 960, of which 173 was a loss by resignation, 78 by death and 709 by suspension. Many foreign members resigned owing to the burden of meeting the dues resulting from the decline in the value of currency in the countries in which they lived. Of the 9,128 members, 18 are honorary, 6,956 full members, 839 associates and 1,315 junior associates. Three past presidents died during the year 1923—Robert W. Hunt, Horace V. Winchell, and Albert R. Ledoux; Edwin M. Ludlow dying in the present year.

The treasurer reported gross receipts of \$208,433.04 and gross expenditures of \$198,036.14 and a valuation of assets of \$725,062.89 of which \$141,031.37 was in various funds, \$41,993.01 in cash and \$5,940.02 in paper on hand.

WILLIAM KELLY NAMED PRESIDENT

The tellers announced through the secretary that William Kelly, of Vulcan, Mich., was elected president; E. L. De Golyer, of New York City, and C. W. Merrill, of San Francisco, vice-presidents and directors. The directors elected were R. V. Norris, Wilkes-Barre, Pa.; G. O. Smith, Washington, D. C.; P. B. Butler, Joplin, Mo.; B. D. Quarrie, Cleveland, Ohio, and L. D. Ricketts of Warren, Ariz. Both the amendments to the constitution received almost unanimous adoption, that to Art. II, Sec. 2, receiving 1,719 favorable to 194 unfavorable votes and that to Art. III, Sec. 3, receiving 1,484 ayes to 424 noes. About 50 unmarked ballots were thrown out in each vote. About a third of the membership voted on the Mellon taxation plan, 98 per cent being in favor of its adoption.

H. A. Wheeler advocated a reduction in the number of directors, the replacement of short monthly board meetings by quarterly sessions of longer duration and the payment of directors' traveling expenses, but several directors mostly from New York spoke against the change. R. A. Parker, of Denver, Col., wanted the board to be elected locally and not at large even though the country is districted and directors have to be chosen in certain numbers from each district.

A large number of members attended the excursion on the last day to the Bethlehem Steel Works. They were

shown the 424 Kopper ovens, each of a capacity of 13½ tons consuming 7,000 tons of coal daily and producing 5,000 tons of coke, 45,000,000 cu.ft. of gas, 175,000 lb. of ammonium sulphate, 50,000 gallons of tar and 18,000 gallons of light oils. Five kinds of coal are used in these ovens after mixing. They visited also the blast furnaces of which there are seven at the Lehigh plant, the mixing plant and two 200-ton basic tilting furnaces. The visitors also saw the rolling mills and were entertained by the Steel Works at a buffet lunch.

European Methods Contrasted With American

George S. Rice, in the principal address of the first session of the joint committees on Coal & Coke, Ground Movement & Subsidence, compared the method and conditions of the European collieries with those of America, using many lantern slides to illustrate his remarks. His first picture showing the Wemyss (pronounced Weems) Colliery showed how close some of the mines were to tidewater; so close in fact, as to make a railroad almost unnecessary. Mr. Rice said that in Great Britain and in Europe generally the coal did not seem to have the bone which makes the washing of coal such a difficult undertaking in the United States. Washers that give good results in Great Britain might not serve as well here.

In Great Britain the dump must be at least 80 yd. from the head of the shaft, Mr. Rice said. In France, Belgium and Germany as also in Great Britain steel arching was preferred to concrete wherever the pressure of the roof was extreme. It had the advantage of flexibility. In the latter country, at least, corrugated iron had been used for lagging, this on the suggestion of the Henry Louis.

DUSTING NOT COMPULSORY, BUT USED

A slide showed a chalk stripping in France where chalk was being mined for grinding into dust for use in immunizing the mines from explosions. The chalk contains many flints. These are not crushed but separated from the chalk and used for road material. Rock dusting is not compulsory in France but is quite generally used, nevertheless.

Mr. Rice also showed some oil mines in Alsace. In earlier days mines had been opened in the oil shales but the accidents had been so frequent that they were abandoned. Later the shales were drilled and a part of the oil abstracted in that manner. When the oil thus obtainable had been extracted

mines again were opened. The drilling had reduced the gas pressure and with good ventilation, it was possible to work them safely. The roof and shale were extremely rotten and in some mines it was necessary to board up the working face except where the shale was being removed. In others, forepoling only was required, but the work was quite difficult and expensive.

Narrow passageways were driven through the shale and the oil seeped out and ran in channels underneath the track to the shaft where it was pumped to the surface. The risk of explosion was naturally greater than in coal mines and the use of picks was forbidden for it was feared that they might spark and ignite the gas. The rock worked hard on the face but broke easily when released from the mass. Every precaution had to be taken for the gas had a much lower explosive limit than methane. The Germans opened the mines but the French were now continuing their operation. Mr. Rice said that it was the intention to remove all the shale so as to give an opportunity to recover all the oil.

The speaker also showed several of the destroyed and renovated mines and explained how the shafts were repaired by cementation, diving bells with peep holes in certain instances being lowered into the water from which to observe the condition of the walls of the shaft. He also showed some liquid-oxygen blasts in quarries, explaining that these explosives had been used in coal mines by the Germans.

It is believed that they had many explosions from this cause, but as they occurred during the war, no word of them reached the public. He said that they should not be used in underground coal mines as they gave out much flame. He added that sometimes powdered coal was used with the liquid oxygen as the material the oxygenation of which produced the blast.

At the opening of the meeting, H. Eustace Mitton, member of the Council of the (British) Institution of Mining Engineers was introduced by the chairman, Howard N. Eavenson, and made some remarks. Dr. R. V. Wheeler, Director British Safety-in-Mines Station at Eskmeals, Cumberland, England, detained by an investigation of a recent disaster, was unable to be present.

Subcommittees on Industrial Relations Report

During the year 1923, according to B. F. Tillson, assistant superintendent, New Jersey Zinc Co., and chairman of the Safety Subcommittee of the Industrial Relations Section in a report made to that committee, the number of chapters of the Joseph A. Holmes Safety Association grew from 35 to 81 and probably is now between 85 and 90. These chapters are distributed through the mining camps of some fifteen states in this country.

Although during the past year the coal industry has had nine serious disasters, which caused the death of 287 men, yet many advances have been made in coal-mine safety practices and installations, based at least to a certain extent on suggestions and experi-

ences in connection with the serious coal-mine disasters which occurred during the latter part of 1922 and the early part of 1923.

The principal causes of these major mine disasters were: The use of open lights, the use of black blasting powder, and the sparking of electrical apparatus. Open lights in three major disasters resulted in the loss of 109 lives and in three minor disasters caused the death of three and the injury of 21 other men. Black powder caused in two major and three minor disasters the death of 24 men. Sparking electrical apparatus caused two major disasters and the death of 147 men.

Use of rock dust for restriction or prevention of explosions has been taken up in earnest, especially in the western states; at one mining camp alone over six miles of underground haulageway has been rock-dusted and nearly 2,000 V-troughs for rock-dust barriers have been placed at strategic points underground.

EXPLOSIVES REDUCED 25 PER CENT

Permissible explosives have been substituted in a number of mines for black powder; mines which had been blasting with miners on shift are now restricting blasting until the end of that working period; other mines which were blasting after the main shift, but had permitted the holes to be loaded by miners while on shift, have adopted the practice of not allowing any explosive in the mine during the regular working hours, the holes being both loaded and fired after the shift. Some coal mines have adopted a system of air spacing in blasting holes with intent to increase the percentage of lump coal and decrease the quantity of slack and of dangerous fine dust sent into the air. The result has been very satisfactory as the objects outlined have been accomplished and at the same time the quantity of explosive has been reduced 25 or more per cent.

Some coal mines are experimenting with the use of storage batteries, not only for gathering purposes, but also for main haulage and for undercutting machines, the intent being to remove electric power wires from the mines, or at any rate, from the vicinity of the working places.

Sprinkling systems for the wetting of mines have been greatly extended. In 1923 one company laid nearly 35 miles of water lines underground for sprinkling purposes. Every working place in these mines has its water line and is provided with about 20 ft. of rubber hose, the man working at the face being required to wet the coal before shoveling it into the car and also to sprinkle the top of the car when loaded.

The practice of using a water spray on the cutting chain of shortwall undercutting machines in coal mines has spread rapidly and not only makes the air of the place practically dustless while undercutting, but also makes the dreaded "bug dust" harmless. In fact the wet "bug dust" helps to kill the dust from subsequent blasting and shoveling.

A new permissible electric cap lamp has been placed on the market and its lighting capacity is said to be equal to that of the ordinary carbide light. It

has the advantage over the carbide lamp that without attention it furnishes light throughout the entire shift. This lamp may replace open lights in both coal and metal mines as it will not cause fires or explosions and it gives better light than other safety lamps, and at least as good as ordinary open flame lamps, and does not require attention during the shift.

A number of coal mines have removed from use all flame safety lamps except those magnetically locked and equipped with automatic or friction igniter.

For use as auxiliary power for main fan operation in case of failure of the primary power, gas or kerosene engines are being placed in such manner that the auxiliary power may be applied to this fan within a very few minutes after interruption of primary power. One coal company has created a new position not only giving the experienced mining man, who has been appointed, charge of safety work but also full operating authority. Hence he has power to enforce immediately such action as he sees fit to recommend as needed to assure safety.

Among the numerous activities of the U. S. Bureau of Mines as to health and safety in mines the following may be mentioned:

Ventilation and dust studies were continued in metal mines and extended into coal mines and much interesting data collected as to the effect of various kinds of dusts (silicious, non-silicious, coal dust, or a mixture of coal and rock dust) upon health. Also, a study was made as to the effect upon underground workers of practically continuous breathing of small quantities of carbon monoxide.

NEW DUST SAMPLER INVENTED

A new method was developed for the sampling of dust from air with special applicability to mine air in coal or metal mines. The instrument is called the Impinger and its principle is the forcing of the air samples through a fluid, thus filtering the dust out of the air and leaving it in the fluid where it is available for later analytical work.

An extended study was made, in underground openings, of frictional coefficients in connection with air flow under various conditions. The U. S. Bureau of Mines also instituted during the year what is known as Safety Service work under which bureau engineers, after making mine inspections, furnish confidential written reports to the operator embodying the conclusions of the engineer as to the condition relative to safety with recommendations as to betterments.

Arthur Notman, consulting engineer, of New York City, reported for the subcommittee on Employment and Industrial Organization, setting in action a lively discussion on immigration and of the proposed law for the further restricting of the entry of aliens. B. F. Tillson declared that the industries of the United States, judging from past records of immigration, were at least 1,500,000 men short of these requirements and added that the law, by admitting more Northern Europeans, was not providing for any relief; for none of these men would perform common labor. He saw no hope except in the

raising of wages to such a level that the man who labored with his hands would be better paid than the man who was engaged at brain labor. Some questioned whether the Southern Europeans were inferior in any way to the Northern and said they were more desirable because inured to labor. Those Europeans who had neither Asiatic nor African admixture in their blood were capable of becoming citizens of great value to the country though they might be below our educational standards.

E. A. Holbrook, Dean of Mining, Pennsylvania State College, made a report on education for the subcommittee, of which he was chairman. This report, made partly to "sell" the advantages of safety to the American Institute of Mining and Metallurgical Engineers, was a masterly study of the economics of mine accidents and is well qualified to "sell" the safety idea to those who do not yet realize its importance as an engineering study in mine operation. It will be published later in *Coal Age*.

SAVINGS IN COMPENSATION

In brief, it showed that if rates for compensation as high as 2.1 per cent of the total cost of operation were reduced to 0.91 per cent the difference in cost between the extremes at a mine employing 500 men would be about \$17,000 per year. He added that the average time lost owing to temporary compensable accidents in Pennsylvania alone was equivalent to 899,958 man-days. "This means," he said, "that 3,600 men are supported constantly who are doing no work."

Dr. R. R. Sayers, chief surgeon, U. S. Bureau of Mines, was not present but sent a paper entitled "Observations on Health Conditions in Mines of Foreign Countries. Most of his references were to diseases and conditions found in metal mines. He said, however: "In view of the health hazard due to breathing silicious dust, the question of safe rock dust is much discussed in Great Britain.

"Mortality statistics of workers have been carefully studied. On the basis of these studies, certain dusts have been found to be relatively harmless, at least no more harmful than coal dust, all investigators being agreed that limestone dust is the safest, especially if it contains a percentage of magnesium. Shale dusts of varying composition are used in some coal mines for dusting purposes without apparent harm to the men exposed.

"Animals have been subjected to various types of dust and the effects noted. Dr. A. Mavrogordato, of South Africa, believes that it is possible to determine the relative safety of breathing a given dust within three months by animal experimentation. Dr. W. E. Guy, of London, thinks that the time required would be at least one year. However, they use different methods and the time for reaction might vary accordingly."

As to fatigue, Dr. Sayers said: "Dr. C. S. Myers, of the National Institute of Industrial Psychology, states that he has been able to decrease the fatigue and increase the efficiency of coal miners by training the men to use the pick properly. Dr. Myers advises a

slower stroke in picking coal but a faster stroke in picking down hard stone." Sidney Rolle, U. S. Metals Refining Co., Carteret, N. J., presided at the meeting.

Ways of Lowering Mine Costs And of Bettering Coal

Mining by the "V" system was described by Glenn B. Southward, chief engineer, West Virginia Coal & Coke Co., at the Coal meeting held under the chairmanship of Howard N. Eavenson, consulting engineer, Pittsburgh, Pa. *Coal Age* has so completely described this method in an article which appeared Feb. 7 on pages 197-203 that much further elaboration is not needed. Mr. Southward said:

"The design was perfected in the summer of 1921 by myself, and a trial face was started in December of that year. This was intended mainly as a test on the mechanical equipment and a preliminary experiment on roof action. During these experiments, development was started for the "V" system but because of the six months' interruption by a strike, mining on the "V" faces was not begun until late in 1922. The trial's on the "V" system continued through an experimental period of several months and by March, 1923, we were convinced that an operating system had been devised. Since that time no changes have been made except in details. These were introduced to increase efficiency and reduce cost.

STRAIGHT FACES WERE FAILURE

"During the experimental period straight faces were tried but they failed. The first trials on the "V" system were with faces 100 ft. long and a central angle of 90 deg. This made a span of 160 ft. from point to point. With these dimensions the beam effect was not obtained; the span was too great and the roof action was practically the same as when straight faces were used. It was some time before this fact was fully accepted, because it was always possible that the failures on the 90-deg. angle were caused by ineffective timbering or improper methods. Several procedures were thoroughly tried; these involved different sizes and spacing of posts, cribs and packwalls, also different timing of roof falls. Falls over large areas and over small were duly tried, but the results were practically the same in every case—the top fell inside the points and along the faces."

Speaking about falls which trespass on the working faces Mr. Southward said, "The falls do not generally come to any extent within the points, except where the top is weak. As such times, the face conveyors are shortened to a point of safety and mining is not interrupted. The output is decreased for only one or two days, for the faces are lengthened on each succeeding cut after the fall and soon regain their full length." He added that the first panel was close to the outcrop and that the outside faces were therefore under light cover. In consequence the roof would not span the normal width, and it was thought best to shorten this length of span by shortening the faces. This left

a narrow pillar unmined but no more coal was lost than would have been left in had the room-and-pillar method been used under similar conditions. Mr. Southward continued:

"The plan described is a combination of conveyors and mine cars, but it is doubtful if this is the most efficient or the most desirable arrangement. A plan is now under consideration, and experimental work on it is being started, to extend the conveyor system all the way to the tippie, thus eliminating all mine-car haulage. Because of the increased output per employee and the consequent reduction in the houses required, also by the elimination of all track, haulage and gathering locomotives and reducing the number of mining machines and pumps, it has been estimated that the cost of installing an all-conveyor mine should be from 25 to 40 per cent less than that required for a room-and-pillar mine of the same output. This, however, is mainly theoretical at this time."

EIGHT UNITS WORK INDEPENDENTLY

Speaking of the flexibility of the system Mr. Southward said, "With 600 ft. of working face in an area 300 ft. wide, there are eight separate operating units and an interruption on any one of these faces does not affect the operation of the others; whereas with a long single face a fall or other interruption may stop the entire output until the trouble is removed. In case a fall should occur within any angle so as to close a face completely, it would not be necessary to reopen this as the coal in the point could be recovered by lengthening the adjoining face on the next cross-entry."

In answer to questions, Mr. Southward said that on each face four or five daymen were employed. He declared there was too much waste thrown among the timbers to make their recovery economical. As to the possibility of caves should the mine operation be irregular, he said that about July 4, 1923, the mine was idle for 10 days and when work was resumed no change was observable. However, a fall had occurred just before that suspension relieving the pillars from a considerable part of the weight. A fall is made every 60 ft. He could not say what would happen if a fall were left hanging when work was suspended. It would not be good engineering to permit this to happen. The mine runs on a two-shift basis, the coal being loaded in the day and being cut and shot at night.

PREFER MECHANICAL PRECIPITATION

Ray W. Arms then read a paper on the "Dry Cleaning of Coal" for which no space is available for reprinting at this time. The paper is well worthy of publication and will appear in an early issue of *Coal Age*. Mr. Arms frankly admitted that difficulties had been experienced at McComas, W. Va., in the sizing of the coal and in the collection of dust similar to those detailed by Frank Young in a paper describing the brilliant plant at Raton, N. M., published in *Coal Age*, May 17, 1923, pp. 791-797. These difficulties have been overcome. The air-cleaning machines at McComas and Wyco, W. Va., have a

larger capacity than those at Raton. The reduction of ash in coals of various regions has varied from 46 to 64 per cent, No. 2 buckwheat from the Pennsylvania anthracite field having exhibited the larger reduction. The ash which was 18.7 in the crude coal becoming 8.5 per cent after treatment. Mr. Arms said that Mr. Nesbitt, of Pittsburgh Pa., had favored electrical precipitation of the finest dusts but after investigation had decided that mechanical precipitation by baffles was preferable.

E. M. Chance described the Chance system of cleaning coal by floating it in a quicksand maintained at a given density. He advocated the crushing of the rejects from one flotation tank and their washing in another so as to prevent clean coal being lost by being dragged down by bone or slate. The coal could be crushed in its entirety but that would prevent the production of any coarse coal and add unduly to the sizes under $\frac{1}{8}$ in. that cause the formation of slimes which it is hard to separate from their interstitial moisture.

Accident Reduction Sought in Forum with Safety Council

Three notable addresses on safety in mining occupied the joint session of the Industrial Relations Committee with the Mining Section of the National Safety Council, Feb. 19. R. Dawson Hall was chairman. Among these papers, that by W. W. Adams on "Mine Accident Statistics" was perhaps the most important. Mr. Adams has combined the reports made by members of the National Safety Council in a series of tabulations giving far more detailed information, perhaps, than previously has been available. Certainly, it has this transcendent importance that it stretches across state lines and so combines the experience of many fields.

This paper will be published in *Coal Age*. It shows, what may not be universally true, that the haulage hazard is greater in the rooms than on the haulage roads. As the chairman declared, the figures lead to the conclusion that the gathering hazard is greater than the main-haulage risk. It seems possible that there will hereafter be less gathering by mules and locomotives. When coal is brought by conveyors to the main roadways this hazard will be eliminated, and as it shows itself to be extremely important its eradication will be a great gain for safety.

When B. F. Tillson at the autumn meeting of the National Safety Council suggested that the cars might be kept in the main roadways, thus making a car with a larger wheel base feasible in accord with A. J. Hoskins' suggestion, he probably did not realize how close the development of the conveyor brought that improvement. A few short months have convinced the industry that conveyors are well justified and a notable reduction in the gathering hazard may result. Cars, as the chairman said, may not have to be uncoupled either in the mine or indeed outside of it provided the rotary-dump or the bottom-dump car is introduced. Fur-

thermore, larger cars on straighter tracks may have a larger wheel base and may be equipped with better brakes. Is it too much to hope that they may be actuated by air, which will come into action at the will of the motorman, or if a car or cars become uncoupled? Better haulage conditions may result; more than counteracting the increase of hazard from that source which recent years has shown. In fact, here again, better engineering and greater economy will mean increased safety.

Speaking of the gas and dust explosion hazard, John T. Ryan said that in the northern field of France not a single man had even been burned by a gas explosion since 1917, showing an almost unbelievable progress in the avoidance of the explosion hazard. Dean Hollbrook asked Mr. Greensfelder if fuses could be so arranged that they could not be cut off at improper lengths. Mr. Greensfelder believed that this would be difficult. Furthermore, he said that it would have to be taken up with the fuse companies, fuse not being manufactured by powder firms. It was suggested that the coal companies sell the fuse in suitable lengths for blasting. The chairman thought that this might make matters worse, compelling the man who wanted to use a "skin-em-back" to use a half length which might be shorter and more risky than the length he would otherwise use. R. N. Hosler suggested that the use of fuse be abandoned entirely, and J. J. Walsh declared that electric batteries soon might be required by law in Pennsylvania mines, the increased safety more than compensating for the cost.

MAGNETIC ROPE TEST COMPLICATED

R. L. Sanford read a paper on "Magnetic Investigations of Hoisting Rope," saying that the purpose was to test the rope by some simple magnetic method as it traveled up the shaft. Unfortunately, the rope was under strain in the act of hoisting and that strain varied with the position of the rope in the shaft and with the acceleration or retardation of the cage. As the magnetic qualities varied with the strain and changed sign during an increase in load, and as parts of the rope might be in strain as laid in the rope and released from strain when the rope was stretched, the subject was quite complicated and not to be settled without careful investigation, which he was making in the hope that some way out of the difficulty might be found.

He said in answer of W. R. Chedsey that electrical resistance was a poor way of determining the condition of the rope, for it varied with the contact between the wires in the strand and the lubrication. The current had to cross between the strands and a well-lubricated rope might behave like one that was severely rusted. Mr. Chedsey asked Mr. Sanford's opinion as to the use of high-frequency currents in rope testing, and the latter replied that with such frequencies there was what is known as a "skin effect," the current tending to follow the outside of the rope which was just the reverse of what was desired. We can form visually some idea of the condition of the exterior of

the rope, but of the interior we know nothing till we cut and destroy it.

H. Foster Bain's paper on "The Bureau of Mines' Work for Safety," read in his absence by T. T. Read, brought out the fact that our keen desire for industrial accident-prevention work was consequent on the amelioration of the other hazards of life. This had brought out in bright light the dangers of industry. When sixty million men died from smallpox in Europe in the limits of a single century (the Eighteenth), when murder was so common that men shook hands with the idea of disarming an appearing friend but possible enemy, no one but the victim cared much about a chance accident or death that might happen as a result of the careless actions of some fellow worker or employer. "Industrial hazards," said he, "now come out in relief just as the candle shines when electric lights are turned off."

ACCIDENT RELIEF CONSIDERED

Mr. Bain said that the desire was universal to "do something" about mine accidents. The work of the Bureau was to ascertain what that "something" should be. He said, "Under our system of dual government, regulatory powers in the mines rest with the states but, where prior to formulating regulations, extensive and expensive research in technical matters is required, there is obvious economy in the states acting through the Federal government, and thus avoiding duplication and disagreement. The Bureau spent approximately a quarter of a million dollars in its five years' work at the experimental mine on dust barriers. Obviously it would be poor economy to have each of the 29 coal-mining states duplicate this work, and though the amount spent may seem large it is to be remembered that the property damage alone in one coal-mine explosion is often larger."

T. T. Read then read his paper on "Mental Hygiene in Industry." He remarked in his summary "that the engineer will not have attained the full measure of a man until to the fairly complete mastery he has attained over mechanical forces he had added a corresponding degree of mastery over the other, less measurable but no less potent forces that act on human beings who are the most important factors in industry."

In the round table which followed, Mr. Pallister declared that inquiry should be made into the possibility of radio causing the premature explosion of blasts, such explosions having been caused a quarter of a mile from a high-power radio station.

What Australasia May Teach

Fresh from a sojourn in Australasia, Dr. A. J. Lanza, at the final session of the Industrial Relations Committee, gave an interesting account of labor conditions in Australia and New Zealand where the workers intent on governmental operation of all industry deliberately seek to make operating conditions unbearable with the idea of forcing government ownership.

Strikes are deliberately arranged, not for the correction of grievances actual

or imagined, but solely for their effect on the morale of the management; here today, there tomorrow and at a third mine the next day. The antagonism between labor and capital has reached a chronic stage.

Doctor Lanza said that only two plants had attempted industrial relations work, but it had been successful where introduced. He emphasized the importance of studying the historical background of these disagreements and believed that the conditions in Australia were the outcome of long inherited antagonisms. It is not to be supposed that the larger mines lacked change houses or favorable working conditions. The metal mines certainly took good care of their men, taking temperature readings and dust counts and providing excellent circulation of air. That could not be said of the coal mines, which, strange to say, in Australia lagged behind the metal mines, doubtless because the former were smaller operations and because the metal mines had found it necessary to combat the dangers of silicious dust.

Speaking about nystagmus, Doctor Lanza said there was none of it in metal mines but the coal mines had it. J. W. Paul suggested it might come from using hand lamps and hanging them up. The glare from the suspended lamp in the darkness might cause the spasms of the eyeball, termed nystagmus, but Doctor Lanza said the lights were carried in many ways. In response to a question by R. D. Hall, he said he was not ill-disposed to believe that some germ might be the cause of nystagmus. The spasmodic movement of the eyeball from right to left and left to right was so marked, no one could suggest that the disease was one of imagination or malingering.

REPRESENTATION NOT NECESSARY

Robert E. Tally's paper was read by Arthur Notman, the chairman. Mr. Tally who is connected with the United Verde Copper Co., Jerome, Ariz., said his company had no employee's representation. "This plan," he said, "is very satisfactory for large organizations, and also for such small companies as have their work scattered over a large area. However, there are conditions under which such a plan is not necessary."

L. K. Silcox, of the Chicago, Milwaukee & St. Paul R.R., not being present, his paper was read by Sidney Rolle. He laid emphasis in this paper on the historic development of the labor unions through the merchant, craft and yeoman, or journeyman guilds. He declared that "many lessons and inferences might be drawn from the industrial evolution of England, not the least of which is the utter futility of legislative action as a means of augmenting a change, and that open rebellion or forceful reaction has but slight influence upon the general trend, for it is a recognized fact that great national crises have left but slight impress on society, while important changes have taken place slowly and by almost imperceptible development." That is to say, only the history of evolution, not the history of events, counts in the life of the race.

Opportunities for Mining Engineers Canvassed

What changes in the mechanical equipment of collieries will do to advance the interest of the mining engineer in coal mines was the subject of R. Dawson Hall's address at a joint meeting of the institute with the Mining & Metallurgical Society of America, held under the chairmanship of B. B. Gottsberger, of Yale University.

After detailing the revolutionary changes sure to arise from the introduction of the conveyor and the mechanical shovel, Mr. Hall said, "Clearly where such changes are taking place, there is room for men who have an ability to grasp new ideas and practices and to perfect them. The 'Cousin Jacks' of metal mining have their duplicates in the coal industry, and unfortunately the latter industry has never had the benefit of the extensive introduction of technical graduates which has marked and modified the development of metal mining. Most of the colleges are laying more stress on metal than on coal mining, though there is probably equal opportunity in both. It will be almost impossible to make a successful rebirth of the coal industry without a large incursion of technical men."

FOREIGN MINING NOT HOPEFUL

T. W. Finch spoke about the "New Fields for Mining Engineers in Foreign Countries," but was not particularly hopeful. In China, Americans are soon replaced by native technicians, who may not devise new methods, but can adopt those already in operation. In Russia and Siberia, Americans are welcome to operate the properties that local capital cannot handle or which local opinion regards as of dubious value. Coal is China's chief asset, but already many companies are in the field.

L. W. Mayer, a banker, discussed "The Engineer's Relation to Bankers." He said that the engineer had as yet neither properly evaluated his services nor was he duly valued by the investment world. When advertisements for bond issues were published, the lawyer's approval of their legality appeared but the engineer's name did not appear. The engineer in fact was usually not well enough known to carry due weight with the public.

He declared that the banker engaged the attorney without inquiring his charges; whereas when he looked for an engineer he shopped around and took care to see he got the lowest figure. The lawyer's fee he regarded as a charge he must prepare to meet, however high. The engineer's fee was something he could beat down to the lowest figure. In fact, the engineer entered the industry mainly because it appealed to his lust for adventure and travel and the lawyer because the profession promised lucrative reward.

The engineer's judgment was as good as the lawyer's or the banker's especially as to his part, the cost of the plant, but he usually failed to consider the overhead, the cost of legal advice and of getting the capital and the heavy charge for interest between the

time of acquiring the capital and arriving at the estimated production.

N. C. Rockwood urged in his paper the needs of the rock-products industry for engineers who would study its problems as carefully as engineers had studied those of coal and metal mining and metallurgy. Even the sand business needed geological, mechanical and marketing study.

Who's Who in Safety

What the foreman and the workman can do to vitalize and drive forward a safety movement was emphasized by two speakers at the final session of the Industrial Relations committee, Feb. 20. At this meeting, Sidney Rolle presided. The first paper, entitled the "Vital Factor in Industrial Relations," by G. M. Gillette, was read by Mr. Rolle. The author pointed out that in all industrial organizations the foreman was the direct point of contact between the management and the workers. He is the go-between, so to speak, and must represent the company to the employee and the employee to the company. If he is a man of vindictive character, this fact will sadly detract from his usefulness as a foreman. If, on the other hand, he is a man of kindly and sympathetic disposition, with the ability to lead and not drive, he may become a potent factor in averting industrial strife.

INDUSTRIAL PLAN SUCCESSFUL

In discussing this paper, W. R. Webster, of the Bridgeport Brass Co., stated that his firm adopted the industrial plan at the direct suggestion of the United States Government. It has, however, worked successfully. The company representatives in the deliberative body, established under the industrial plan, are almost invariably foremen. Matters of plant safety are placed entirely in the hands of a committee which is held strictly responsible for all accidents. This also has had a decidedly beneficial effect.

The plan has also done much to reduce radicalism and has served effectively in transferring the viewpoint of the company to the minds of the workmen. It is highly effective as a means of education. Why one man is paid more for his services than another is a mystery to most workers. When it is explained that the services which the higher priced man renders are more valuable than those of the man lower paid, much rabid radicalism disappears.

Mr. Lavine stated that behind the non-commissioned officer to which the foreman had been likened was inflexible justice. Mistakes in the management of industrial concerns often bring on strikes, working to the disadvantage of all concerned. The ordinary worker desires responsibility and when it is given him, much of his radicalism vanishes. Regardless of the efficiency of the foreman, the management must sell itself and its fairness to its men.

(Additional interesting discussions and some of the articles read will appear next week.)

Stockpiles of Soft Coal Near Peak Jan. 1
With 62,000,000 Tons

Two Million Tons Added Since Oct. 1—Supply Would Last 46 Days at
Current Rate of Consumption—Retailers' Stocks of
Anthracite Increase 60 per Cent

Consumers of bituminous coal had reserve stocks of 62,000,000 tons of that fuel on Jan. 1, 1924, according to a survey by the Bureau of the Census and the U. S. Geological Survey. The year just passed was one of practically uninterrupted accumulation of reserve stocks, and the inventory at its close revealed the following facts: Stocks on Jan. 1, 1924, were 2,000,000 tons larger than on Oct. 1, 1923, and about 6,000,000 tons larger than Sept. 1. In comparison with corresponding dates of preceding years, stocks on Jan. 1, 1924, were 72 per cent larger than in 1923, 29 per cent larger than in 1922, 35 per cent larger than in 1921, and even exceeded those on Jan. 1, 1919, by 7 per cent. In fact on only two dates for which stock records are available has the present supply been exceeded—Armistice Day, 1918, and April 1, 1922, on each of which dates stocks totaled 63,000,000 tons.

Measured in terms of tons, stocks increased 3.3 per cent during the last quarter of 1923. Measured in terms of days' supply, the increase was 2.2 per cent, the percentages being based on averages which assume that the supply was evenly distributed. In the estimate, which is based on reports from a selected list of about 5,000 consumers, no account has been taken of coal in the bins of householders, concerning which no statistics are available; nor steamship fuel, nor the tonnage on the Lake docks, which item is classed as coal in transit.

In addition to the quantity estimated as in storage piles of actual consumers, the following quantities are known to have been in transit on Jan. 1: On the commercial docks of Lakes Superior and Michigan, 7,800,000 tons; in storage

at the mines or at intermediate points, 390,000 tons; unbilled loads at mines or en route to consuming centers, 790,000 tons.

As shown graphically in Fig. 1, coal consumers had larger stocks at the beginning of 1924 than on any corresponding date for which records are available. In comparison with dates on which reserves were large, the stocks on Jan. 1, 1924, were 18 per cent larger than those on March 1, 1922, 28 per cent larger than those on Nov. 1, 1921, 35 per cent larger than those on Jan. 1, 1921, and but 2 per cent less than those on Armistice Day, 1918, when record stocks were available. The present stocks, even though less than at the close of the war, are more adequate, for the rate of consumption is now somewhat less.

Estimates based on the reports from consumers and supplemented by information from other sources indicate that consumption plus exports in the last quarter of 1923 was at the rate of approximately 10,200,000 tons per 7-day week.

Stocks in Days' Supply

Fig. 2, which is based upon data in the table herewith, compares the days' supply held by the seven principal classes of consumers on Jan. 1, 1924, with that on the same date two years ago. The importance of the rate of consumption in determining the adequacy of stocks is shown here, for had the rate of consumption on the earlier date been equal to that now prevailing, the supply on Jan. 1, 1922, would have been sufficient for less than 35 days instead of the 41 days shown.

The average stocks on Jan. 1, 1924, were sufficient to last 46 days, at the

rate of consumption in the last three months of 1923, against a 45-days' supply on Oct. 1. Despite the increase of 6,000,000 tons in actual tonnage, the supply on Jan. 1 was sufficient for only the same number of days as that on Sept. 1, 1923, owing to an appreciable increase in rate of consumption. In terms of days' supply the stocks on Sept. 1, 1923, and Jan. 1, 1924, are the highest recorded. It should be remembered, however, that any change in the consumption rate since Jan. 1 will be reflected in the days' supply.

Fig. 3 offers a graphic presentation, by states, of the variations in stocks. The map shows the days' supply held at general industrial establishments, excluding byproduct coke plants and steel works. This is the largest single group of consumers and the one that illustrates best the geographical distribution of reserves. Changes in business activity in this group are quickly reflected in the coal market, and, likewise changes in the coal market are soon manifested in the stocks held by general industrials.

Over the country as a whole the stocks held by industrial plants on Jan. 1 were sufficient to last 55 days on the average, a decrease of one day from the supply on Oct. 1 and Sept. 1. Here, too, the importance of consumption is strikingly shown, for the actual tonnage held by this group on Jan. 1 was about 8 per cent larger than on Sept. 1. In comparison with Oct. 1, however, industrials had a somewhat smaller tonnage on Jan. 1.

The distribution of stocks between states, as shown by the map, is typical of dates when reserves were heavy and business active. The entire territory east of the Mississippi had at least a 30-days' supply, except in Illinois, West Virginia, and Maryland, coal-producing states where consumers are close to the mines. Reserves were heaviest in New England, the Upper Peninsula of Michigan, and the Atlantic Coast states. The smallest stocks, as usual, were in that belt of states which extends west from Illinois through the center of the country to the Pacific Coast, and in the

Days' Supply of Bituminous Coal in Hands of Various Classes of Consumers, Nov. 11, 1918, to Jan. 1, 1924 (a)
(Figures represent number of days supply would last at current rate of consumption at time of stock taking)

	Nov. 11, 1918	Jan. 1, 1919	Jan. 1, 1921	Nov. 1, 1921	Jan. 1, 1922	Mar. 1, 1922	Jan. 1, 1923	July 1, 1923	Aug. 1, 1923	Sept. 1, 1923	Oct. 1, 1923b	Jan. 1, 1924b
Byproduct coke plants.....	35	32	29	38	42	39	19	26	27	30	33	35
Steel plants.....	45	42	42	46	48	48	27	35	35	33	39	43

Coal dealers, bituminous.....	37	39	30	46	33	33	16	39	45	38	36	34
Railroads.....	31	32	23	31	35	35	16	28	39	44	41	44
Total bituminous.....	45	42	39	43	41	41	26c	37c	44c	46c	45c	46c

(a) The figures in this table are estimates based on incomplete data. (b) The rate of consumption used in calculating the days' supply on Oct. 1, 1923, and Jan. 1, 1924, was the quantity consumed from Oct. 1 to Dec. 31, 1923. (c) Subject to revision.

Fig. 1—Total Commercial Stocks of Bituminous Coal, Oct. 1, 1916, to Jan. 1, 1924

Figures represent million net tons and include coal in the hands of railroads, industrial consumers, public utilities, and retail dealers. Coal for steamship fuel, on Lake docks, in transit, and in the bins of householders is not included. These exceptions are important, the coal on wheels having proved at times a greatly disturbing factor in the calculations of would-be statisticians.

lignite-producing states of Texas and Montana.

The map in Fig. 4 compares, state by state, the tonnages held by industrials on Jan. 1, 1924, and on the same date in 1922. In 26 states stocks increased at least 5 per cent. whereas decreases to that extent occurred in but 14 states. Practically the entire eastern section of the country and the Southwestern States were particularly well supplied when compared with 1922, and appreciable decreases were confined to the Northwestern and Rocky Mountain States.

Reports from the electric-utility plants show preceptible increases in stocks during the last four months of 1923, but consumption increased to even a greater extent, and the 51 days' supply available on Jan. 1, 1924, would have lasted one day less than the supply on Sept. 1. The tonnage held by such plants on Jan. 1, 1924, was considerably larger than on that date in 1922, but owing to the greatly reduced demand for electric power then prevailing, the smaller stocks were sufficient for the same number of days' consumption.

Reserves at coal-gas plants increased

somewhat during September, and remained practically stationary during the remainder of the year. The days' supply of gas coal decreased sharply from 110 days' on Sept. 1, to 91 days' on Jan. 1. This decline may be attributed to the usual seasonal increase in the demand for gas during the fall and winter months. In spite of the decrease, stocks on Jan. 1 were larger than on any corresponding date for which figures are available.

Complete returns from the byproduct coke and steel plants showed the following reserves on Jan. 1, 1924, at the rate of consumption prevailing from Oct. 1 to Dec. 31, 1923, and on Jan. 1, 1922:

Byproduct Plants

	Jan. 1, 1924	Jan. 1, 1922
Low volatile.....	41 days	54 days
High volatile.....	33 days	38 days
Average.....	35 days	42 days

Steel Works

	Jan. 1, 1924	Jan. 1, 1922
Steam coal.....	35 days	41 days
Gas coal.....	60 days	58 days
Average.....	43 days	48 days

Fig. 2—Days' Supply Held by Different Classes of Consumers, Jan. 1, 1924, and Jan. 1, 1922

At the rate soft coal was burned in the last quarter of 1923, total stocks on Jan. 1 were sufficient to last 46 days, an increase of 1 day over the supply on Oct. 1. Stocks on Jan. 1, 1922, were sufficient to last 41 days at the rate of consumption then prevailing.

In terms of tons byproduct coke plants had a 40-per cent larger reserve on Jan. 1, 1924, than on that date two years ago, and the stocks at steel plants were 7 per cent larger. The larger stocks were more than offset by the increased rate of consumption in 1923, and when expressed in days' supply the reserves at byproduct plants fell 17 per cent, at steel plants 10 per cent.

The railroads accumulated coal steadily during 1923, and on Jan. 1, 1924, had on hand an enormous total of approximately 19,000,000 net tons, the largest quantity ever recorded, excepting only stocks on April 1, 1922, when the railroads had stored about 19,800,000 tons in anticipation of the strike. This supply, which includes the coal in stockpiles, cars and chutes, was sufficient to last 44 days, a supply equal to that on Sept. 1, 1923, despite the regular seasonal increase in consumption.

The demand for soft coal for household purposes increased sharply with the arrival of winter weather, and stocks held by retailers declined from 38 days' supply on Sept. 1 to 34 days on Jan. 1. The reserves held by retailers at the beginning of the year com-

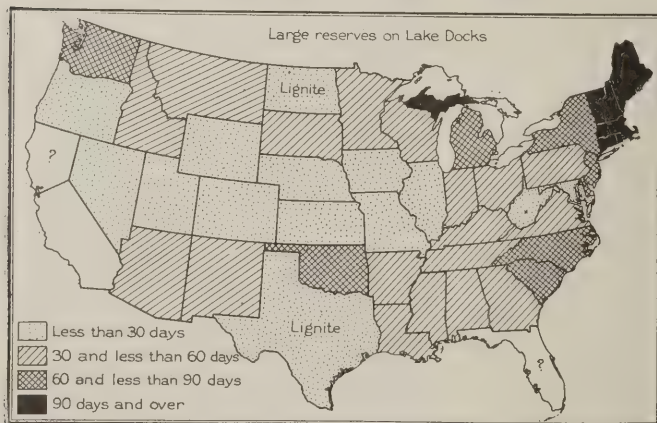

Fig. 3—Days' Supply of Bituminous Coal on Hand at Industrial Plants, Jan. 1, 1924

At the average rate of consumption that prevailed during the last quarter of 1923, reserve stocks at industrial plants, other than steel and byproduct coke, would have lasted on the average 55 days. Of the states east of the Mississippi only West Virginia and Maryland had less than a 30-days' supply. New England and the Upper Peninsula of Michigan had supplies sufficient for 90 days or more. Based on reports from 2,210 plants.

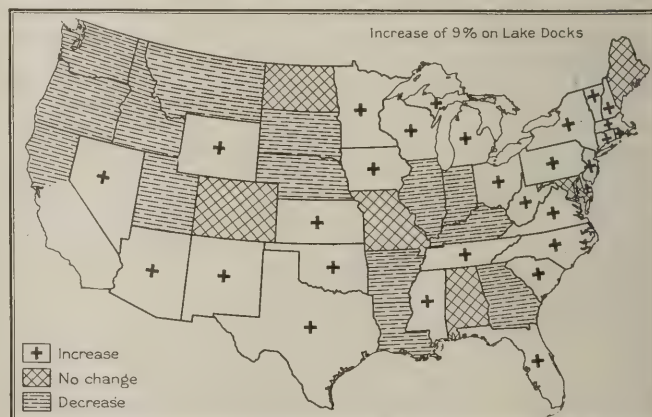

Fig. 4—Stocks of Industrials on Jan. 1, 1924, Compared With Those on Jan. 1, 1922

The map shows the changes in tonnage on hand at 1,846 identical industrial plants other than steel and byproduct-coke works. Industrial plants have steadily added to their reserves since the close of the miners' strike in 1922. In 26 states the quantity held on Jan. 1, 1924, was larger than it was on the corresponding date two years ago, when coal was being accumulated in anticipation of a strike.

pared favorably with those on other winter dates.

Lake navigation remained open unusually late in the season just passed, and receipts of soft coal during the last quarter of 1923 exceeded shipments off the docks by 14 per cent. Stocks on Jan. 1, 1924, were 7,805,533 tons compared with 6,861,706 tons Oct. 1, 1923.

Reports from an incomplete list of producers who store, showed that the quantity held by them decreased from 440,000 tons on Sept. 1, to 375,000 tons on Oct. 1 and 385,000 tons on January 1. Unbilled coal standing in cars at the mines increased from 470,000 tons to 786,000 tons in the same period.

Stocks of coke at byproduct coke plants decreased from 501,000 net tons on Sept. 1 to 476,000 tons on Oct. 1. Coke was accumulated during the last quarter of 1923, however, and on Jan. 1, 1924, the total on hand was 772,000 tons. This is the second largest figure on record, being 22 per cent less than that for March 1, 1922, the date of record stocks of coke.

Anthracite—Retail dealers' stocks of anthracite increased during the last three months of 1923, and their total supply on Jan. 1 was about 60 per cent more than on Oct. 1. Reports from the docks on Lake Superior and Lake Michigan that handle anthracite showed a total of 513,000 tons on Jan. 1. The production of anthracite was interrupted by a general anthracite miners' strike for about two and a half weeks in September and by the occurrence of holidays in November and December. Demand for domestic sizes continued brisk up to the close of the year, and the mines worked close to capacity whenever possible. Since Jan. 1, production has fallen off slightly.

Facts relating to production and retail dealers' deliveries indicate that householders' stocks probably are normal for this time of year. The tonnage produced flowed steadily to the consumers practically as fast as it could be mined, and retailers were not able to build up their reserves to normal until midwinter.

Retailers' receipts exceeded their deliveries during the last three months of 1923, and their reserves on the first of the year had increased sharply over those on Oct. 1. It has not been possible to make a canvass of all the coal dealers, but reports from a group of 474 who have reported regularly since Jan. 1, 1919, show a total of 1,063,277 net tons on Jan. 1, 1924, against 663,340 tons on Oct. 1. This was an increase in tonnage of approximately 60 per cent. In terms of days' supply the increase was 60 per cent.

Stocks of anthracite on the upper Lake docks increased during the last three months of 1923, the total on Jan. 1 being 65 per cent larger than on Oct. 1.

Production of bituminous was maintained at a high rate during January and February, and it seems probable that coal has continued to flow into storage. Anthracite production has declined slightly since Jan. 1, and as severe winter weather has prevailed in many parts of the country, it seems likely that retailers' stocks have decreased somewhat.

Western Kentucky Consolidation

Frank D. Rash, president of the St. Bernard Mining Co., of Earlington, Ky., announced on Feb. 19 that there is a deal pending, which probably will be closed within thirty or sixty days, for the sale of his company's property in western Kentucky to the North American Co., of New York, owners of much public-utility and associated property throughout the Middle West, including the West Kentucky Coal Co., of Sturgis, Ky., with eleven western Kentucky mines. This deal would bring the two largest west Kentucky mining groups under one control. Mr. Rash is to remain with the company.

Denies Scandal in Transfer Of Alaska Coal Lands

Colonel John R. Steese, of the U. S. Army Engineers and chairman of the Alaska Railroad Commission, who was in Buffalo Feb. 18 to speak to army men, said that there was nothing illegal or scandalous about the transfer of Matanuska coal lands from the Navy Department to the Interior Department. He labeled as "bunk" the charges made by John E. Ballaine, Alaska Railroad contractor, in a letter to President Coolidge, that the transaction paralleled the Teapot Dome affair.

"After the Navy Department had spent about \$1,500,000 in the development of these coal regions, the big oil discoveries of 1914 were made in California," said Colonel Steese. "The navy decided then to use oil as fuel and power in the Pacific fleet, because of the reduced price of oil, and as a result abandoned the Matanuska coal regions. The natural consequence of the abandonment of these lands was that the lands were then classified as 'public domain' and properly referred to the Department of the Interior. As I understand it, Secretary Fall, while head of the Department of the Interior, attempted to dispose of the coal lands to private interests, but in a proper, legal manner.

"The lands were public domain and any private persons or corporations could acquire a lease to the regions under a leasehold from the Department of the Interior."

Factory Will Make Mine Loaders Exclusively

Because of the importance of mechanical loading, a factory exclusively devoted to the manufacture of underground loading machines has been provided by the Joy Machine Co. A celebration was held Feb. 9 to mark both the completion of the first of its new heavy-type loading machinery and the opening of the factory at Evansville, Ind. The company claims that this is the first factory dedicated to the sole purpose of producing this important adjunct to mining equipment. Already 200 Joy loaders are in service.

Supreme Court Sets Aside Addy Conviction

Conviction of the Matthew Addy Co. and Benjamin N. Ford, its vice-president, on charges of violating the Lever Act by selling coal at a higher margin than fixed in the Presidential proclamation of Aug. 23, 1917, was set aside by the U. S. Supreme Court in a decision rendered Feb. 25. The defendants are coal jobbers of Cincinnati.

Under a contract dated July 31, 1917, the defendants bought coal from the Bluefield Coal & Coke Co. at \$3.25 per ton f.o.b. mine in West Virginia. They were convicted of selling some of this coal in August and September, 1917, at \$3.50 per ton, f.o.b. mine. The margin fixed for jobbers in the Aug. 23 proclamation of the President was 15c. per ton.

In reversing the District Court and the Circuit Court of Appeals, the Supreme Court declared that the proclamation of Aug. 23 was not retroactive and that the transaction was begun before the proclamation was issued. "No imperative reason appears for treating jobbers who had bought but who had not contracted to sell with less consideration than was accorded those with agreements for sale irrespective of the stipulated price," the opinion stated.

Sandefur-Canoe Creek Case To Be Argued April 7

The Supreme Court Feb. 25 granted a motion to advance the case of S. C. Sandefur against the Canoe Creek Coal Co. and assigned the case for argument on April 7. Sandefur was convicted of contempt of court by the U. S. District Court of Western Kentucky for violating an injunction restraining strikers from interfering with employees of the coal company. He demanded and was refused a jury trial. The Circuit Court of Appeals of the Sixth Circuit, to which an appeal was taken, has asked the Supreme Court for instructions as to whether Sec. 22 of the Clayton Act, which requires a conviction upon a jury trial as a condition precedent to punishment for contempt, upon demand for a jury in the case specified, imposes a valid restriction upon the inherent judicial power of the U. S. district courts, as the appellant insists. It is upon this point that arguments will be made in April.

Another African Coal Field

The discovery of coal at Stamprietfontein, about forty-five miles from Marienthal in the mandate territory of Southwest Africa, has been reported. The seam is said to be 14 ft. thick and was discovered at a depth of 143 ft. in one of the government boreholes. It has been traced for four or five kilometers, but the exact area of the coal field is uncertain. Some doubt seems to prevail as to the successful development of any coal discovered in Southwest Africa, the chief difficulties being those of transport and the question of labor, as the local natives (negroes) are much averse to working underground.

Dominion Miners Ratify Pact And Return to Work

The pact between the provisional executive of the United Mine Workers for the eastern Canada district and the British Empire Steel Corporation (Dominion Coal Co.) has been ratified by most of the miners who went on strike for increased wages one month ago. The question was voted on by the various locals in the United Mine Workers for the affected territory, and the striking miners decided by a fairly large majority to return to work. The agreement between the executive and the company heads provides for a 5 per cent increase in wages and no reduction in the banking periods.

The Stellarton local, one of the most powerful locals in the district, voted strongly against returning to work and demanded the return of the 1921 wage agreement. Provisional President Barrett and International President Lewis were assailed at the various meetings held by the miners. Phalen local, of Glace Bay, although scoring the officers and eulogizing the deposed secretary, J. B. McLachlan, now serving a two-year term in Dorchester (N. B.) prison, the most radical local of all, agreed to return to work. Provisional President Barrett threatens to expel the Stellarton local unless the members of that local return to work within ten days.

Rocky Mountain Engineers Talk Safety

Safety first, last and all the time was the central theme of the 18th regular meeting of the Rocky Mountain Coal Mining Institute, at Denver, Feb. 13 to 15. It was the keynote of President George B. Pryde's address on Wednesday morning, the opening day, and it ran on down through most of the program, although other matters also were covered.

On Wednesday afternoon papers were read by L. S. Ickis on "Automatic Substation Control," relating primarily to equipment for automatically regulating rotary converters and motor-generator sets. Mr. Ickis' paper, and that following, "Beautification of Industrial Towns," by S. R. De Boer, a prominent landscape architect of Denver, were illustrated by lantern slides.

Mr. De Boer's discussion was particularly interesting to the Wyoming delegates, who see so little of trees at home. Mr. De Boer stated that a considerable amount of beautification could be done at a small expenditure. He also discussed the planning and arrangement of small cities.

Following Mr. De Boer, Thomas Foster, superintendent of the Union Pacific Coal Co.'s operations at Reliance, Wyo., read a paper entitled, "Coal Dust in Mines." This is a live subject to the mines in the Rocky Mountain region, where the air is so dry.

The banquet to members and their ladies was given Wednesday evening in the Cathedral room of the Albany Hotel. Pliny F. Sharp, one of the youngest old members of the organization, presiding as toastmaster, kept his audience in high humor introducing E.

Joseph Struthers

Secretary of the Engineers Club and former secretary of the American Institute of Mining and Metallurgical Engineers, who died of pneumonia, Feb. 18.

N. Weitzel, a past president; George B. Pryde, president, and Colonel Philip S. Van Cise, the District Attorney for Denver, so well known in the West for his recent conviction of the infamous Bunko gang. Colonel Van Cise spoke on "The Problem of the Criminal."

The Rocky Music Coal Players then presented "The Silly Selling Singers Symphony," in "The Coal Bloc, a Ton of Unscreened Fun," written by Nobudi Will Admittit, arranged and directed by Forrest Rutherford. "The Coal Bloc" is a one-act comedy detailing a meeting to nominate a candidate to represent "coal" in the coming presidential race. After the show, a large crowd remained to dance.

The Thursday morning session began with the report of the Safety Committee; President Pryde, chairman. The report was thoroughly discussed by many members. In the afternoon, R. L. Hair, division superintendent of the Colorado Fuel & Iron Co., described the "Mine Sprinkling" methods in use by his company. Dan Harrington, of the U. S. G. S., told of the safety measures being taken at the Phelps Dodge Co.'s mines at Dawson, N. M. He described the Dawson mines as the safest he had ever seen.

The Friday morning session was devoted to the reading and discussion of a paper on "Use of Overcutting Machines," by T. A. Stroup, superintendent of the Utah Fuel Co.'s Clearcreek mine. Friday afternoon the following officers were elected: President, William Littlejohn, general superintendent of the Utah Fuel Co.; vice-president for New Mexico, Horace Moses, general manager of the Gallup-American Coal Co.; vice-president for Wyoming, E. S. Brooks, vice-president and general manager of the Union Pacific Coal Co.; vice-president for Colorado, James Dalrymple, State Mine Inspector; vice-president for Utah, John Forrester, chief engineer of the U. S. Fuel Co.; secretary-treasurer, Benedict Shubart, of Denver.

U. S.-British Co-operation Sought for Mining Safety

While there are barriers, real or imaginary, to close political co-operation between nations, there are no obstacles to close international relationships between those engaged in technical and scientific work. This is one of the thoughts developed by speakers at a luncheon, Feb. 25, tendered Dr. R. V. Wheeler and W. R. Chapman by George S. Rice, chief mining engineer of the U. S. Bureau of Mines. Dr. Wheeler and Mr. Chapman are in this country to complete arrangements for a definite program of co-operation between the United States and British governments on matters pertaining to safety in mining. Dr. Wheeler is director of the British Government's experiment station at Eskmeals and is professor of fuel technology at Sheffield University. Mr. Chapman is a chemist attached to the technical staff at Eskmeals. Henry Walker, deputy chief inspector of mines for Great Britain, who will assist in these arrangements, had not arrived in America in time to attend this luncheon.

In the course of remarks at the luncheon, Director Bain, of the Bureau of Mines, pointed out that when the Bureau of Mines was created its research program was based to a considerable extent on information that had been developed by the British. Since that time there has been some informal co-operation between the Bureau and the British agencies engaged in similar work. Much good, he said, had resulted from the informal work and it gives a measure with which to estimate the much greater benefits likely to flow from the formal relationship which now is being entered upon. He spoke of the desirability of close relationships along professional lines.

Dr. Wheeler, in his remarks, declared that the Bureau of Mines has been the ideal toward which comparable activities of the British Government are striving. It has been only since the passage of the Mining Industries Act, he explained, that the British agencies have been in a position to hold up their end of such a proposition, the act providing funds for research.

Again Ask Change of Venue In Armed-March Case

As in other counties, where cases growing out of the armed march of 1921 in southern West Virginia have been tried, the defense in the case of the State of West Virginia against C. F. Keeney, president of District 17, United Mine Workers, as a last resort has applied for another change of venue and sought permission of Judge J. W. Eary in the Circuit Court of Fayette County to obtain affidavits to show that the defendants could not obtain a fair trial. The motion was overruled by the court on the ground that the defense had already had ample time to obtain such affidavits without waiting until the time set for the trial. The cases have dragged along for three years largely as a result of frequent changes of venue.

Long Step Toward Stabilization in 3-Year Contract Is Washington View

Regret Felt That It Fails to Provide for Modifications as Conditions Change—Keen Competition Likely to Cause Rapid Elimination of High-Cost Mines

By PAUL WOOTON
Washington Correspondent of *Coal Age*

The three-year contract agreed to by miners' union officials and soft-coal operators of the Central Competitive Field is regarded in Washington as a decided step forward. The ideal condition, in the opinion of most officials who have special knowledge of coal, is to have long-time contracts, but with provision for a certain amount of flexibility to take care of changing conditions. Regret is expressed that no start was made in that direction in this contract. It is believed generally, however, that experience under this contract will be such as to pave the way for the automatic rise and fall of wage scales to follow the real value of money.

All are agreed that the next three years will be ones of strenuous competition and painful readjustment. Competition already has reached a point that calls special attention to the great expansion which has taken place during the past seven years in the coal-producing industry. The elimination of high-cost mines will proceed at a much more rapid rate from this time forward.

The situation has brought with it a demand that the industry keep watch on the rate of its own expansion. It is suggested that the National Coal Association could perform a helpful service to the industry and to the public if it were to compile and keep up currently basic information with regard to the opening of new mines. It is believed that in normal times comparatively few new mines would be opened if the total amount of expansion in progress were known. Even under present prospects when many relatively low-cost operations are facing an uncertain future, it is known that new mines are being opened and that many other new mines are in prospect.

If the real facts were known, it is believed that the operators themselves would be inclined to defer new enterprises, but the principal influence of exact information would be in retarding the banks and other financial interests from backing such propositions.

The situation with regard to new coal mines is much like that which overtook the raisin growers. A few years ago, they took advantage of a propitious situation to boost the price of their product to an artificially high level. This caused existing vineyards to expand their acreage and induced an army of farmers to embark in vine growing. The resulting overproduction led to staggering losses.

In many industries the financing is so centralized that a careful check is kept on expansion. Most new coal mines are financed in the immediate locality. The backers, as a rule, have no conception of the number of properties being opened in similar fashion. It takes a couple of years for a new

coal mine to reach the point where it really begins to produce. By that time it may be evident that there is overproduction of coal, but then the capital investment is so great that production must proceed at the sacrifice of profit and in some instances at actual loss.

With the situation which now impends there is new reason for information in regard to new mines to be generally available. Production has proceeded for a long period without interruption. Stocks are large and three years of peace stretch ahead. In addition the country's consumption of coal is not increasing at the same rate maintained during the twenty years preceding 1919. The higher coal prices which have prevailed over a period of seven years have turned the attention of the consumer to economies in the use of coal. It formerly was so cheap that there was no incentive to attempt to eliminate waste.

The elimination of waste in fuel, however, now has reached the point where it is almost the rage. Very material economies have been effected. The Geological Survey reports show, for instance, that during the last five years there has been a reduction of 25 per cent in the amount of coal necessary to produce a kilowatt hour. The coke industry has gone from a beehive to a byproduct basis. The gas that once was wasted is now being burned under boilers and in furnaces. The International Railroad Fuel Association points to some very striking savings in the increased number of locomotive miles attained. A great wave of hydroelectric development is under way. The enormous production of petroleum has a deeper significance than the actual coal displaced by fuel oil. It has curtailed a large amount of new business which would have come to the coal com-

panies. An example is the retarding of electric line development, due to the use of the automobile. The bunker business is rapidly being lost.

All of these things taken together have resulted in a decided flattening of the curve indicating the average rate of increase in coal consumption.

Under contracts of one and two years, strikes or suspensions were frequent enough to have some stimulating effect throughout the period of the contract. They offered enough encouragement to the new small mine to keep the crop large. The hope now is to acquaint the prospective operators of such properties with the fact that a very different situation now faces such enterprise. If this can be brought home to them, it is recognized that a long step toward stabilization will have been taken.

British Columbia Gloomy Over Coal Industry

"Disabilities and Problems of the Coal Mining Industry of British Columbia" was the subject discussed at the opening session of the annual meeting of the Canadian Institute of Mining & Metallurgy (British Columbia Division) held at Vancouver Feb. 13-15. The addresses of Charles Graham, of the Canadian Collieries (D) Ltd.; C. M. Campbell, of the Cassidy Collieries, Granby Consolidated Mining & Smelting Co.; J. P. Biggs, of the Mines Department, and R. M. Young, of the Crows Nest Pass District, were somewhat gloomy in their general tone.

Owing to fuel-oil competition, the decrease in the export trade and the carriage of coal in ballast by vessels coming to Vancouver City for cargo, the industry, it would appear, is passing through a crisis. Mr. Graham pointed out that the provincial production in 1923 was 600,000 tons less than in 1910 notwithstanding an increase in population and in manufactures.

Reference also was made to the cost of production in the Comox district of Vancouver Island, chiefly because of the shale found with the coal. In speaking of the speculative character of development it was said that an instance had occurred where three boreholes a considerable distance apart apparently had tapped a 17-ft. seam of coal, but when actually opened up it was found that in each case the drill had struck a pocket and all the expenditure had been lost.

Mr. Campbell dealt with the Cassidy Mine. Half of the area being exploited, he said, did not contain coal and the coal measures were badly faulted and the development expenses very heavy. As to the Nicola-Princeton field, it was stated by Mr. Biggs that, though there were no very extensive deposits, the area was important. Production in 1923 had been 233,000 tons.

Discussing the Crows Nest field it was said by Mr. Young that the once prosperous industry there had been hurt by reason of the adoption by American railroads of fuel oil. It also had suffered through the removal of the Granby smelter from Grand Forks to Anyox and by the substitution of electricity for coal at the Trail Smelter.

Wage Cutting in This Field?

The Kentucky-Tennessee Coal Operators' Association and the United Mine Workers have been unable to agree on a new wage contract for operations in southeastern Kentucky and eastern Tennessee, the operators refusing to renew the old contract as a result of being in a field that is not fully organized and that is in competition with several unorganized fields. Over the past several months the union agents have been working hard in an effort to organize the miners in the Harlan, Pineville, Middlesboro and surrounding districts, but have not made much headway.

Practical Pointers For Electrical And Mechanical Men

Application of the Diesel Oil-Burning Engine to Coal Mining

About a year ago I was called upon to make a recommendation for a power unit at a coal mine. After looking over the requirements and conditions at the mine I decided that a Diesel oil-burning engine would be entirely suitable and could be used at low cost, at the same time obviating the necessity for expensive maintenance. The engine therefore was installed and has since proved quite successful, but the application of the Diesel engine to a mine power plant is so novel that the question might reasonably be asked, why use a Diesel engine at a coal mine?

To answer this question a short description of the plant may be necessary. The mine is the property of the Laurie Coal Co. located at Vaughan, Nicholas County, W. Va. The power unit is a 125-hp. three-cylinder Selzer-Bush Diesel engine, direct-connected to a 75-kw. 220-volt direct-current Westinghouse generator. Compressed air at 700 lb. pressure is used for starting and is supplied by an Ingersoll-Rand compressor belted to the flywheel of the engine, and stored in four tanks. Fuel oil also is stored in a nearby tank and fed to the engine as required.

The selection of this equipment was based upon economy and simplicity of operation and low maintenance costs.

Economy of operation is the outstanding feature of this power plant. An ordinary isolated steam power plant required for producing the power requirements of this mine would use about 5 tons of coal per day, which at \$2 per ton would make a total of \$10 a day for fuel. The Diesel engine described above consumes 29 gallons of fuel oil per day, which at 6c. per gallon costs \$1.74, a saving of \$8.26 per day, or \$65.20 for a working month of 20 days.

The steam plant would require an engineer and fireman at a total cost of about \$300 per month, whereas the Diesel engine requires the attendance of one man at a cost of about \$175 per month, a saving of \$125 per month. Therefore the fuel and labor saving is \$290 per month or \$3,480 per year.

The operation of the plant is very simple, the engine is started and stopped at will and requires only the turning on of the air and fuel valves and regulation of the mixture to operate it between the limits of no-load to full-load. With a steam plant the boilers must be started some time be-

fore the plant can turn out electrical energy, the delay being from one to five hours, depending upon whether the fires must be newly started or have been previously banked. Compared with the steam engine with its power plant the Diesel engine has few moving parts and is readily accessible for repairs.

The maintenance costs for a Diesel engine are unusually low; repairs consist of replacing small parts and the work can be done very quickly when compared with the time required to take a boiler out of service and make the ordinary repairs which must be made to a boiler plant.

With these many advantages in its favor the application of the Diesel engine at the afore-mentioned mine has proved quite successful and the experiences here no doubt will help to establish its use in the mining field.

WILLIAM SCHAFER,
Electrical Engineer.

Charleston, W. Va.

Tests of Insulating Varnishes

Standard tests have not been developed to measure all the qualities of varnishes but all the important controlling characteristics can be measured and the others approximated from observation and comparison. As no varnish can possess all the desirable qualities to the maximum extent, it is necessary to consider the varnish from the standpoint of the use that is to be made of it and interpret the test results with the view of selecting the most suitable varnish for the purpose in mind.

Specific gravity is a measure of the weight of varnish in relation to that of water. The determination gives a figure that expresses this weight but does not take into account the factors that make it up. High specific gravity might indicate by itself either a high percentage of base (oils and gums) or a solvent of high gravity combined with a normal percentage of base. It is not an indication of the volume of covering or filling material per gallon, or, in other words, of the proportion of base and solvent.

Viscosity is of principal value in comparing samples of the same or similar varnishes. This characteristic is greatly affected by the heat treatment given the oils in the varnish and is not a true indication of the

proportion of base and solvent. It is, however, an important factor affecting the thickness of coating produced by the varnish.

Flash point indicates the probable nature and volatility of the solvent or, in the case of varnishes having a blended solvent, the volatility of the most volatile flammable ingredient.

The evaporation test indicates the relative quantities of solvent which will be lost through evaporation and which will have to be replaced to maintain the varnish at the proper consistency in the dipping tank. This is a factor affecting the cost of using the varnish.

We now come to the point where we must consider the changing features of the varnish as it passes through its other phases toward hardening. As a general rule, the varnishes are applied by dipping until the pieces treated are well saturated. They are then withdrawn from the bath and allowed to drain until the setting stage is reached. At this stage some of the solvent has evaporated and the viscosity of the varnish base is sufficient to stop the flow.

The draining test is of great value in indicating the working characteristics of the varnish during this time. It is important that the various elements be so combined that the thickness of film on surfaces and the volume throughout a mass be as evenly distributed as possible from top to bottom. Of course, mechanical means, such as turning the pieces, may be resorted to, but this takes time and adds to production cost. In such arrangements as conveyor ovens it is next to impossible.

The thickness of coating is controlled by the viscosity, percentage of base, volatility of thinner and speed of withdrawal. When a coil is withdrawn from the varnish, the quantity of liquid varnish then adhering to it is governed by the original viscosity of the varnish itself and the speed of withdrawal. As draining begins, the relation of values is constantly changing, due to the continual evaporation of the solvent, until the time comes when enough solvent has evaporated to allow the inherent strength of the varnish base to maintain stability. Then movement ceases and setting really begins to produce a final outside film which gradually hardens.

It should be remembered in this connection that rapidly evaporating solvents give a shorter flow, and varnishes containing them show a greater increase of deposit from top to bottom of the treated piece, while heavier sol-

vants tend to give longer flow and therefore a more uniform thickness of coating. A solvent of too high a distillation range would introduce objectionable features. For instance, it might slow the drying and affect the enamel or enameled wire.

The time-of-drying test is important, as the results of the other tests may be affected greatly by it. Varnishes dry by evaporation of the solvent and oxidation and polymerization of the oils. Oxidation begins at the surface and progresses inward. Most varnishes contain drying agents to accelerate oxidation, and, due to differences in composition, the drying characteristics may not be the same.

A strong drying action may produce surface drying, which would be indicated by a hard surface free from tack and soft unoxidized varnish underneath. This is an undesirable characteristic and in determining the drying time and preparing the test specimens, precautions should be taken to make sure that the varnish is hardened throughout. Testing the film with the finger nail and examination of the bead or fatty edge give some indications as to the degree of skin hardening as compared to that throughout the mass. It is to be noted that hardening is progressive and continues to the point of final break-up of the varnish at the end of its usefulness.

Dielectric strength, unfortunately, cannot be determined as accurately as would be desired. Although in the tests two dip coats producing four separate films of varnish are specified, it is difficult to obtain a perfectly uniform continuous coating. Dust present in the varnish, or settling on the test specimens while draining, and small air bubbles will produce minute perforations in the film and lower the dielectric strength. The degree of baking also has an important bearing on the dielectric strength. As the varnish hardens through baking, the dielectric strength increases, and in making this test it is important that all varnishes be hardened to the same extent. All films must be of the same thickness, as thinner films harden better and show a higher dielectric strength per mil.

The water-absorption test is of great value, probably being second only to the heat-endurance test. While it is subject to the same conditions affecting the dielectric-strength test, the latter test affords a correction factor, for the reduction in dielectric strength due to immersion in water is the basis of comparison in the water-absorption test. It is important that the films be of the same thickness and of the same degree of hardness. The loss in dielectric strength apparently is governed by the depth to which the water penetrates and the measured dielectric strength is in reality the dielectric strength of the unpenetrated film. A heavier initial film will give a higher dielectric strength, as there will be a greater thickness of unpenetrated varnish at the expiration of the 24-hour period.

Heat endurance is of great importance and is only relatively indicated by the test. The test is a measure of the time a film of given thickness may be baked and still not break when

stretched a specified amount. It is an indication but not an exact measure of the life of the varnish in actual service. In making the bending test, it is important that the test specimens be cooled to the proper temperature and bent over the rods in a uniform manner. If the test specimen is bent quickly, the varnish film will crack more readily, and the test specimens must be bent around the rods at the same speed to obtain comparable results.

The acid, alkali and oil-resistance tests are in the same category with the water-absorption test and are equally important. While, of course, varnishes may be chosen for their resistance to any one of these products, the ideal varnish would withstand all to the greatest possible degree because it is used to protect the rest of the insulation. In general, varnishes containing fairly high percentages of asphaltic ingredients best resist the action of acids, alkalis and water, while those which are high in the drying oils are found to be the most oilproof.

Acids tend to further oxidize the oils until they are finally burned; alkalis tend to saponify them. The black gums are seemingly very little affected by either and are generally hydrofuge. The hardened oils, however, are only slightly affected by transformer or lubricating oils and even by their original solvents. The oil resistance of any varnish is increased by overbaking. In such a case, one can even obtain an oilproof coat from a varnish containing practically no drying vegetable oils. It is essential, therefore, that the tests for oil resistance be made

on varnishes baked to a uniform degree of hardness in relation to their surface drying times.

The test for non-volatile matter is an indication of the proportion of base and solvent by weight. Varnishes are sold by volume and this test does not indicate the proportion by volume. It is of value in making comparisons only where the varnishes tested are of the same type and have solvents of the same specific gravity. The heavy-gravity solvents show a lower percentage of base when computed by weight, and as the varnish manufacturers use solvents of widely varying specific gravities this test should be used with discretion. It is of value and is frequently incorporated in specifications covering the same or similar varnishes.

Bending of Copper

All bends in copper should be made free and easy, that is, they should be given as large a curvature as is possible in the space available. Where sharp bends and sharp fillets are made, the effects of vibration, expansion and contraction, or the throwing out forces due to rotation show up first.

Frequently sharp bends are made at the ends of copper strap field coils and when making the clamped or soldered joints, in many cases the bad conditions that have been set up are overlooked. The sharp bend, or kink, may later be the cause of a motor failure which could easily have been avoided. It often happens that the armature-coil failure is at a point where the wires have been carelessly bent or crossed.

Bonding to Full Capacity Of Mine Rail

The power lost in the return circuit from direct-current motors used in the mines is no doubt greater than that lost in all the alternating-current circuits feeding other machinery. The track-circuit loss in street-railway systems is so well recognized that it is often claimed that any excessive loss in the track circuit will put a street railway company into bankruptcy.

The track system of many mining companies far exceeds that of a large street railway and the operating conditions are far more severe, and consequently power losses may easily become very great. Poor track bonding causes so many accidents, delays and serious troubles to the mining men that it is difficult to know where to begin to enumerate them. Equipment failures, high maintenance costs, high capital charges and high power bills are only a few of the worst results of poor bonding; in fact it affects the

whole operation of the mine from the morale of the workmen to the cost per ton of coal.

Money spent to provide good bonding soon comes back with large dividends and those men who realize this fact are forever striving to better their mine track conditions. In this respect many engineers are divided on this question into those who believe in bonding the track to the full capacity of the rails and those who rely more on return circuit cables.

Where heavy rails are used the Pennsylvania Coal and Coke Corporation of Cresson, Pa., has lately adopted the use of an extra heavy bond having a capacity equal to a 350,000 c.m. cable. This bond has been installed with great success and is being applied extensively. No difficulty has been experienced by its use, and voltage tests previously described in *Coal Age* have shown good results.

The illustration shows the type bond now being used. The terminals are steel jacketed and are easily applied to the rail by electric welding.

Large Capacity Rail Bond

This rail bond is designed so as to obtain the full current carrying capacity of the rails and thus greatly reducing the expense of large return cables.

Production And the Market

Conservative Spirit Pervades Soft-Coal Market; Many Consumers Are Relying on Stockpiles

Buying of coal moves along conservative lines, having settled down to a hand-to-mouth basis in some markets, particularly where anthracite domestic sizes are consumed. The Jacksonville agreement assures peace in the Central Competitive Field for the next three years. Users of hard coal will buy during the next month only to meet immediate needs, as there is no new wage agreement to be negotiated. The little activity and hopefulness that was apparent in the soft-coal industry has nearly disappeared and a spirit of pessimism has taken its place to a degree. Buying has dropped and consumers to all appearances have decided to use their reserve stocks in order to avoid a recurrence of fires in stockpiles which caused more or less trouble last fall. The new working agreement has blasted the hopes of many non-union mine owners who had hoped to realize high prices for their product if there should have been a cessation of work in the union mines. Consumers' stocks on Jan. 1, according to government estimates, totaled 62,000,000 tons.

The average price of soft coal, according to *Coal Age* index dropped 2c. to \$2.23 with an index figure of 184, as of Feb. 25, compared with 186 the previous week.

Cold Weather Has Only Limited Effect

Consumption has been helped in nearly all markets by better coal-burning weather, but there has been comparatively little improvement in general demand. In the Middle West dealers report little buying and demand is generally inactive. Cold weather stimulated the call for domestic lump coal while there is enough screenings available to take care of the demand. Illinois mine owners have "no bills" for all sizes excepting screenings. The mines in the Carterville region are kept in operation because of the continued cold weather

and there is a good demand for Mt. Olive and Standard field coal. No change is reported from St. Louis, where retail dealers are kept busy with the middle grade coals. Demand for Kentucky product is good and some eastern Kentucky mines are sold up for the present. The Jacksonville agreement has injured the prospects of many of these mines, as a general strike or suspension would have meant good prices for these coals.

In the Northwest there is a steady call for coal. The feature of the Duluth market last week was a cut of \$1 in the retail price of Pocahontas coal, bringing the price down to \$8. There has been a slump in the Kansas-Oklahoma territory following the best mid-winter season for several years. The mines are now operating on a three- to four-day weekly basis instead of full time. There has been a let-up in the Ohio steam trade. Consumers are using their surplus supplies and the utilities are practically out of the market.

The clearing of the atmosphere as regards a strike or suspension in the soft-coal fields had its effect on the Pittsburgh market. Coal has become more difficult to sell and some consumers have practically retired from the market. Demand at Boston and throughout New England continues quiet. There have been no market developments. Spot buying is slow and there is not much doing in the contracting phase of the industry. Similar conditions exist along the Atlantic coast. Large reserves preclude the placing of new orders and the prospects are not bright.

Output of soft coal took a slight drop during the week ended Feb. 16, according to the Geological Survey, declining to 11,157,000 net tons, a decrease of 344,000 tons when compared with the previous week, while the output of hard coal dropped to 1,900,000 net tons, a

(a) Revised from last report. (b) Subject to revision.

decline of but 6,000 tons when compared with the week of Feb. 9. The production of soft coal during the first 269 days of the present coal year has been 482,413,000 net tons, as compared with 364,418,000 net tons during the corresponding period of the coal year 1922-1923.

Cold weather and the heaviest storms of the present winter have speeded up consumption of anthracite. Transportation has not been hindered and both wholesale and retail dealers had sufficient coal on hand to take care of the increased demand.

The settlement of the British dock strike has cleared the dark clouds hovering over England and has blocked the hopes of American exporters who expected to ship considerable coal abroad. The local export situation is without special features. There is plenty of coal at Hampton Roads to meet all requirements. A little more activity is noted at Baltimore. Dumpings at Hampton Roads during the week ended Feb. 21 were 360,491 net tons, a decrease of 34,973 tons when compared with the previous week.

Midwest Business Sags

There was no heart in the Midwest coal trade during the past week. Nobody is buying much and nothing is in demand. Cold weather stimulated some trade in domestic lump at a little less than the circular prices, but other domestic sizes dragged and screenings business just barely absorbed the volume of fine coal available. Franklin County lump is on its way down from \$3.75 and the middle sizes are passing \$3 downward bound. Screenings stick at \$1.90@2 and may rise with the inevitable drop in production generally. Central Illinois lump is \$3, with screenings unchanged from last week. Eastern coals are weakening on the Chicago market. Pocahontas lump can hardly command the top price of \$3.75 and mine-run is softening at \$2.50. Good eastern Kentucky lump tends downward from \$3.25.

All Illinois mines had plenty of "no bills" of all sizes, excepting screenings, and these "no bills" kept some mines from working this week. If it had not been for the cold weather mining would have been at a standstill in the Cartersville field. Railroad tonnage is reported light and mines working are getting from two to three days a week, the latter where railroad contracts are included.

The Association operators are holding pretty well to-

Index	1924				1923
	Feb. 25	Feb. 18	Feb. 11	Feb. 26	
Weighted average price	\$2.23	\$2.25	\$2.27	\$3.49	

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

gether, with ore or two cutting prices to the level of the independents. The Association prices are \$3.75 for lump, \$3.50 for egg and \$3.25 for nut, in the country. The independents are selling lump at \$3@3.25, egg \$2.75@3 and nut \$2.50@2.75. Some of the Standard operators are doing as well on sizes as the independents in the Carterville field.

The Mt. Olive situation is considerably improved. There has been a good demand for domestic and the steam is taking care of nut and screenings. Mines work four to five days. In the Standard district conditions have been bad, but are showing up better under the temporary demand, though prices have not improved.

St. Louis Demand Is Fair

Retailers report business in St. Louis fairly good on cheaper and middle grades of coal. A little activity on high-grade coal is seen in isolated spots. Demand is light for smokeless, anthracite and coke. Wagonload steam shows improvement, while the demand for carload steam locally has been somewhat better, especially for screenings. Country domestic is responding to the cold wave, for cheaper grades principally. Dealers are carrying small stocks. Country steam is not a factor and is seldom heard from. There are no changes in retail prices.

Kentucky Lump and Steam Move

Another spell of cold weather is resulting in slightly better demand from retailers for Kentucky coal, coming at a time when the jobbers and operators were beginning to need additional business on prepared sizes, as steam demand has been quite good. Eastern Kentucky mines in many instances are busy and are sold up for a few days to come with the result that prices are fairly steady although it is asserted that the top price on prime block coal has slumped from \$3.75 to \$3.50. Eastern Kentucky has been moving good tonnage into various districts and has been maintaining prices well.

With the signing of the wage agreement at Jacksonville, Fla., last week, Kentucky operators have lost the last chance for the expected general strike, which would have meant big business and good prices to the non-union fields of Kentucky. However, the non-union fields are operating largely on the 1917 wage scale and are steadily underselling union fields, with the result that if there is much business in the spring and early summer they should get a fair share of it.

With the exception of slightly weaker screenings in western Kentucky the market shows no change over the week. Pea, slack and fine screenings are offered at from 90c. to \$1 as against \$1@1.10 as the minimum a week ago. General movement is fair and a full car supply is reported. However, the outlook is for a slow and draggy spring. Many of the operators working under a no-strike contract which has a year yet to run, had been entertaining strong hopes of a national strike this year. One section of the field has a contract expiring on March 31, and there is some question as to whether or not this will be renewed.

Northwest Prices Sinking

The feature of the Duluth market this week is a cut in the price of Pocahontas. One dollar has been lopped off the price, making lump \$8. Run of mine remains the same at \$6.50 and screening are off 25c. to \$5.25. All other bituminous and anthracite coals are the same. Consumers are holding off again, and trade is considered dull. There is about 2,225,000 tons of free coal on docks at Duluth-Superior. This amount is not excessive, and will be fairly well cleared up by the opening of navigation, unless the construction of territory caused by the "unfair" freight rates causes unusual loss in distribution.

The Milwaukee coal market continues on an even and satisfactory basis. The local demand is brisk because of harsh and stormy weather. Country transportation conditions are nearly normal again and orders are being filled more promptly. There have been no important changes in prices at Milwaukee.

Western Trade Slumps

A slump has started in the Kansas-Oklahoma territory following the best midwinter season for several years. Operators report their mines working from three to four days a week, whereas they were working full time. A surplus of all grades had begun to accumulate last week. The surplus of screenings remains little changed this week, but there has been an increase in the surplus of nut and lump. A resumption of price shading further reflects the changing conditions. Folder prices are unchanged, however. Kansas lump is quoted at \$5; nut at \$4.25; mine run at \$3.50 and screenings at \$2.25.

In Colorado the resumption of warm weather has again caused a marked decline in the production and marketing of coal. Mines worked on an average of thirty-one hours for the past week. The operators' weekly reports show that 26 per cent of the full working time was lost on account of no market.

Prices remain unchanged. The transportation and car situation has been favorable except in Routt County, where the mines are experiencing considerable car shortage.

Prices have been shot to pieces in Utah. Operators are cutting 50 to 70c. a ton from mine quotations and dealers' prices have cut from 50c. to \$1.50. The change is on prepared sizes only. Mine prices have been as follows: Lump, \$4.50; domestic lump, \$3.75; stove, \$3.75; nut, \$3.50; mine-run, \$3.50; screen slack, \$1.75; straight slack, \$1.25. A new price circular is expected soon. One cause for the

cut is the fact that three more mutual concerns are trying to get started at Salt Lake City. They have been undercutting the trade 50c. a ton. However, the market is low all around.

Buyers Disappear from Ohio Markets

Buyers in the Ohio markets have practically disappeared since the signing of the Jacksonville agreement. Prices have dropped and the market is extremely quiet. Car movement into the southeastern Kentucky, Big Sandy, Logan County and Kanawha fields, according to reports from Cincinnati, is steadily increasing and most of the mines are reporting about four days a week. Inquiry from Michigan points has slackened. The smokeless operators have been keeping close watch on the British and the French situation. Some contract business is being talked of. Specialized coals are quoted as follows: Egg, \$3@3.25; lump, \$3.75@4.

Operators and brokers in the Cleveland market experienced a decline in business last week. Spot prices show a tendency to weaken but it is not felt that they will go much lower. Since the early part of last week curtailment has been necessary in many operations and production has been considerably cut. The eastern Ohio No. 8 field during the week ended Feb. 16 produced 362,000 tons of coal, or about 52 per cent of potential capacity, which is estimated at about 700,000 tons.

In and around Columbus there was a let-up in the steam-coal trade and large users are scarcely buying current needs. Utilities are temporarily out of the market, while some of the large users of screenings are out of the market because of coal-pile fires. Consumption is about normal, especially in iron and steel industries, while railroad demand is not quite as strong as formerly. Demand for domestic consumption is a weather proposition with a seasonal demand reported from all sections of the state. Dealers are not disposed to accumulate stocks and are buying on a hand-to-mouth basis.

There is absolutely no change in price of coal in the Pittsburgh district or adjacent districts that can be traced to the wage settlement. Sellers have found the market very dull since the settlement, but they had found it practically as dull for a short time before. Consumption of coal is at a high rate. The steel mills are running well and railroad operations are running heavier than in December. Domestic consumption is good, and mine operations in the past few weeks in the district have averaged about 55 per cent.

Since the Jacksonville adjustment forecasts what will be done at a joint conference to be held at Altoona next month, operators in central Pennsylvania are making offers and many inquiries are being received, so that there is little doubt but that the basis for signing up for contract coal can be readily reached.

Trade at Buffalo is quiet notwithstanding heavy snow-falls and stormy weather. There is little activity.

Dull Outlook in New England

The settlement at Jacksonville relieves the last lingering worry of any New England buyers, and doubtless we are in for a long period of dullness. There is little spot buying in any direction, and no consumer with stocks sixty to ninety days ahead can be roused to any immediate interest in the price of coal. Receipts all-rail and by water are about on the average of the past six months, and no marked

increase or decrease is looked for in the near future. Quotas on contract are being accepted reasonably well, but as most of the latter are on a monthly basis, subject to occasional price revision, there is no special significance in the moderate volume coming forward.

Hampton Roads quotations are for the most part unchanged, \$4.75 per gross ton f.o.b. vessel being the asking price of most of the agencies, although there are some who say they are netting \$2.35 and upward per gross ton at the mines for Western business. Likewise there are shippers who are frankly selling for less than \$4.75 at Newport News and Norfolk to move demurrage coal. It is evident that effort will be made to sign up buyers on the \$4.75 basis, a figure that on the 1917 wage scale gives the producer a small margin, but it remains to be seen how nearly stable the market can be made for Navy standard grades.

Pocahontas and New River certainly have the call in practically all the territory here within 100 miles of tide-water. While certain of the factors rehandling coal from cargoes for inland distribution are trying to go through the motions of placing coal at \$6.50 per gross ton on cars Boston or Providence, it is clear that the only actual sales are by those interests willing to accept \$6 as a maximum.

From central Pennsylvania there is only a small tonnage being received by rail and water. The Philadelphia piers show a pronounced slump in the volume dumped for New England, and the New York piers have suffered a similar falling off in business. Except in remote places where Pennsylvania coal can be sold at a moderate freight rate in comparison with market rates from Hampton Roads there are only restricted openings for coal mined on the terms of the union contract.

Activity Lacking in Seaboard Markets

The soft-coal trade along the Atlantic seaboard from New York to Baltimore shows little activity. There are no immediate indications of betterment and buyers are not in the market for heavy tonnages, although there is no surplus of free coals. Contract coal is moving in good volume. At New York receipts at the railroad terminals increased over the holidays but this was to be expected. The prices have not changed materially.

Anthracite Market on Even Basis

The cold weather has kept the anthracite market on an even basis. Demand is regular and wholesale as well as retail dealers are able to keep their stocks moving. Demand, of course, centers around stove and chestnut, but production is more than sufficient to keep consumers supplied. Some of the companies, it is asserted, are storing pea coal. The steam sizes are moving in good volume. Demand for barley is the strongest and some of the independent product of this size is quoted at more than the company schedule of \$1.50.

Foreign Market And Export News

British Coal Market Breathes Easier with Settlement of Dock Strike

Fear that the British coal market would be seriously hampered by the dock workers' strike were quickly dissipated with the announcement that an agreement had been reached, although the men did not return to work immediately. The terms are regarded as a concession to the demands of the men, but they are heartily approved, as they averted what threatened to be a serious labor difficulty.

Output of British coal during the week ended Feb. 9 was 5,804,000 tons, according to a cable to *Coal Age*, as compared with 5,245,000 tons the previous week, or an increase of more than 500,000 tons. The output for the corresponding week of 1923 was 5,567,000 tons.

Exporting of Welsh coals continued uninterrupted, notwithstanding the labor trouble. Demand from foreign buyers was good. Mine owners are looking forward to contract making. Prompt shipments also are reported as easier.

Unfilled orders carried over from January, the threat of a transport strike, and the accumulation of new orders held up by the recent rail strike combine to create a very firm tone. Practically without exception collieries are substantially booked for the next two or three weeks. The demand for early coal is pressing. Inquiry from Europe, Italy and South America is strong. There is little business with Germany but a good demand from the Near East.

Unable to carry out their present commitments, operators are reluctant to accept new business, and in many cases will not take orders for delivery before March. It will be impossible to keep the collieries working fully under the prevailing conditions.

The prospects at Newcastle for February are bright, and all sections enjoy a good demand.

French Coal Market Steady; Demand Fairly Active

The French coal market continues steady. Demand is fairly active and there is a good supply of coal being furnished to Belgium by the Nord and Pas de Calais collieries. The reduction of 3 fr. requested by the government authorities in the prices of all coals effective Feb. 1 widened the range in the selling prices of French and the various foreign coals. Some inconvenience to sellers and buyers has resulted from the recent imposition of restrictions on exports by the government officials, and miners' delegates have been in conference with the Belgian authorities regarding the new rules.

Inquiry for British coals has been dull and the congestion at the British docks had little if any effect on France.

During the first 29 days of January the S.C.O.F. received through Az Ehang and Aix la Chapelle 246,777 tons of coke. The Société des Cokes de Hauts-Fourneaux, which had charge of the reparation fuels, dissolved on Jan. 31, and its successor is in course of organization. It is expected the new price for coke will be 143.5 fr. delivered on the frontier. Deliveries of coke from the Ruhr at present amount to about one-third of the requirements of the French metallurgical industry, making additional purchases necessary from either the French collieries or from British, Belgian or Dutch cokeries.

More Activity at Hampton Roads

Considerable activity in coastwise and foreign movement was reported at Hampton Roads last week, with consequent diminishing supplies at tidewater. Bunker trade was reported fair, but prices continued at a low level, being strengthened but slightly by increased trade.

Inquiries from Italy and South America were reported on an increase, and the prospect for foreign business was brighter than for several previous weeks. Prices at tidewater were proving attractive to foreign shippers, and several good orders were said to have been booked recently.

The tone of the market was somewhat stronger, and there was an indication that trade would improve in the near future. Shippers were optimistic over business during March and April, with prospects of a number of good contracts April 1.

Traffic News

Rate Change to Lake Ports Unlikely This Season

While the prospects favor an ultimate increase in the freight differential from the Southern coal fields to lower Lake ports, as compared with the rates from points of origin in the Pittsburgh and eastern Ohio regions to the same destinations, it is practically certain that no rate changes will be ordered in time to have a bearing on this year's Lake business.

The hearing before the Interstate Commerce Commission at which the testimony of the Pittsburgh and the Ohio operators was taken was concluded Feb. 21. The commission then gave the Southern operators and railroads a period of two months for the preparation of their cases. This unexpected delay in the progress of the case precludes any probability of a decision being handed down before the close of navigation next autumn. This calculation is based on the average time required for the consideration of a case of comparable intricacy.

Burden of Proof of Weight Loss Up to Consignee

In remanding the case for a new trial the Alabama Supreme Court recently held in the cause of James C. Davis, Director General, etc., vs. Samuel Zimmerman, appealed from the Mobile Circuit Court, that the transportation company could not be held liable for loss in weight of coal between shipping point and destination by reason of natural drainage and evaporation, and ruled that the burden of proof of loss other than from natural causes must be furnished by the consignee. The coal in question was shipped from Birmingham district mines to Zimmern at Mobile, Ala. The lower court awarded Zimmern \$2,136.40.

To Construct Lines in Illinois And Kentucky

After reargument, the Interstate Commerce Commission has affirmed the authority granted to the Southern Illinois & Kentucky R.R. to construct lines in Illinois and Kentucky to form, with existing facilities, a continuous line from Edgewood, Ill., to Fulton, Ky. The line is to be operated by the Illinois Central. The new line was justified largely because it gives a particularly favorable outlet for coal.

C. R. & E. Seeks Bond Issue To Improve Line

The Coal River & Eastern Ry. has asked the Interstate Commerce Commission for authority to issue \$500,000 in first mortgage bonds and \$1,000,000 in capital stock for the purpose of completing and improving its line. Of the total, \$550,000 is to be applied on

the purchase of equipment and increasing the weight of rail on the Laurel Creek line as may be required by mine development in that section. The Coal River Collieries is to receive the bonds and \$250,000 of the stock for the railroad property. The remainder of the stock is to be sold to individuals by the Brotherhood Investment Co.

Million Tons of Hard Coal Moved By Lehigh Valley in Month

The Lehigh Valley R.R. loaded 997,601 tons of anthracite during January, 1924, as compared with 1,190,564 tons in January, 1923, and 805,277 tons in the same month of 1922. It was stated at the offices of the company that a comparison with last year's figures is hardly indicative of conditions in that loadings in the winter of 1923 were exceptionally high following the settlement of the anthracite strike, the 1922 figures being more representative of an average month.

\$20,000,000 Cut-Off Again Is Approved

The Interstate Commerce Commission in Washington, on Feb. 16, for a second time approved action of the Illinois Central R.R. in its proposed plan to spend \$20,000,000 in a cut-off line of 169 miles from Fulton, Ky., to Edgewood, Ill., which will materially shorten the distance traversed in direct movement north from Kentucky and the South. The new line will open up a considerable amount of new territory for coal production it is said.

More Promotions on B. & O.

The following changes and promotions have been announced by the freight traffic department of the Baltimore & Ohio R.R. effective Feb. 15: J. L. Hayes is appointed assistant general freight agent, Baltimore, Md., vice George S. Harlan, promoted; R. J. Beggs, division freight agent, Cumberland, Md., is appointed assistant general freight agent, Baltimore, Md., vice H. G. Settle, promoted; C. M. Gosnell, division freight agent, New York, N. Y., is transferred to Baltimore as division freight agent, succeeding Mr. Hayes.

New Locomotives on C. & O.

The Chesapeake & Ohio has begun to put in commission some of its new locomotives, measuring 109 ft. over all, including tenders. These engines will be operated between Hunton and Clifton Forge. Twenty-five of the engines in all are to be delivered, having been built by the American Locomotive Co. at a cost of about \$100,000 each. Each locomotive develops simple tractive power of 103,500 lb., is equipped with 16 drivers measuring 57 in. in diameter and has a total weight of 565,000 lb.

Industrial Notes

The National Engineering Societies has inaugurated a policy calculated to insure the needed funds to provide a **national employment service for engineers**, with offices in leading cities throughout the country. Under this policy the Societies continue their financial support and this is supplemented by contributions from those deriving benefit from this enterprise, as no profit to anyone is to be taken; simply a self-supporting service. Contributions if on a basis of but 25 per cent of the fees which must be necessarily exacted by a commercial agency will make possible the realization of a national service. With the new plan fully developed representatives of the Employment Service will visit those with positions available to get first-hand information as to the requirements of the job. Over 55,000 engineers, including the most prominent of the profession, are members of the Societies conducting the service, thereby ensuring employers a selection from engineers of known antecedents and whose records have been closely scrutinized. Engineers seeking opportunities may arrange to obtain weekly by first-class mail the current list of openings. Their availability also is announced in the respective publications of the Engineering Societies.

Obituary

James Gorman, extensively interested in smokeless coal properties in low-volatile territory, died in Lynchburg, Va., Feb. 18. Mr. Gorman's death was entirely unexpected and the news of his demise was a distinct shock to associates and friends in the southern part of the state. He had for a number of years been associated with J. C. Sullivan in his operations and only recently at the annual meeting of the Smith Pocahontas Coal Co. was named as the head of that concern, operating at Caloric on the main line of the Virginian Ry.

John W. Trounce, vice-president of the Buffalo & Susquehanna Coal & Coke Co., in charge of sales, and vice-president of the Goodyear Lumber Co., died suddenly at his home in Toronto, Ont., Feb. 18, aged 50 years. His death was a great shock to associates in the coal trade, as he had been attending to business as usual in the week prior to his death. He was born at Port Perry, Ont., and as a young man settled in Buffalo, obtaining a position with the Good-year lumber and coal interests, with which he was associated for thirty years. He had a large acquaintance and many friends in the Eastern states and in Canada.

William Donald Clark, well known in coal trade circles in the Fairmont region and construction engineer of the Domestic Coke Corporation of Fairmont, died of pneumonia at the home of his wife's mother at Fairmont during the second week of February. A son of Mr. and Mrs. George A. Clark, of Sidney, N. Y., and a graduate of Cornell University, Mr. Clark became connected with the Domestic Coke Corporation about five years ago. He married Miss Lucille Hart, of Fairmont, on Oct. 30, 1922, and is survived by her and by an infant son, William Donald, Jr., as well as by his parents and one brother, John A. Clark, an official of the Hope Gas Co., of Clarksburg.

Robert Gage, 77, one of the organizers of the Robert Gage Coal Co., of Ray City, Mich., and an owner of Michigan coal mines for years, died suddenly at his home in Jackson, Mich., Jan. 30.

Coming Meetings

Upper Potomac Coal Association. Annual meeting March 3, Cumberland, Md. Secretary, J. F. Palmer, Cumberland, Md.

Northwestern Pennsylvania Coal Operators' Association. Annual meeting March 4, Butler, Pa. Secretary, T. F. Diefenderfer, Butler, Pa.

Canadian Institute of Mining and Metallurgy. Annual meeting March 5-7, King Edward Hotel, Toronto, Ontario, Canada. Secretary, G. C. Mackenzie, Drummond Building, Montreal, Quebec, Canada.

New England Coal Dealers' Association. Annual meeting March 20-21, Boston, Mass. President, W. A. Clark, Boston, Mass.

News Items From Field and Trade

ALABAMA

Four convicts were burned to death in a fire which destroyed the prison at the Flat Top coal mines of the Sloss Sheffield Steel & Iron Co. on the night of Feb. 15. There were about 500 prisoners in the building at the time of the fire, all but four of whom were rescued and held in the prison walls. A number of other buildings in the enclosure also were burned, the total loss being over \$100,000, though no official figures have been given out. The convicts were under the care and supervision of the State Convict Board. It is announced by officials of the company that the building will be replaced as early as practical with a structure of modern design.

S. V. Shelburne, well known in Birmingham wholesale and retail coal circles, suffered the loss of the larger part of his left forearm when he slipped and fell beside the railroad track in the yards of the Pan American Coal Co., of which he is president, when cars were being switched thereon, his arm and hand being so badly crushed under the car wheels as to render amputation necessary just below the elbow. Mr. Shelburne also is president of the Shelburne Sales Co.

It is announced that the mine of the Thomas Creek Coal Co., at Carbon Hill, Walker County, will soon resume operations. The operation has been idle for several months.

ALASKA

First actual demonstration of the value of Matanuska coal for coking purposes was made Feb. 2 when material produced in the ovens of the Alaska Railroad successfully smelted a charge of 4,800 lb. of scrap iron used in castings by the railroad. The coal came from Coal Creek, Chickaloon section of the Matanuska fields. It is pronounced by the foundry foreman as equal to any coke imported from eastern mines. The test finally solves the problem of smelting metalliferous ores, upon which had been pending negotiations for a smelting plant on the railroad.

ARKANSAS

Operation of the Western Coal & Mining Co.'s mine No. 6, near Denning, which had been idle since late in November, when the engine room was destroyed by fire, has been resumed. The hoisting engine was damaged beyond repair, necessitating the purchase of a new one. The mine employs approximately 75 miners.

The Fort Smith Spadra Coal Co., Fort Smith, with a capital of \$100,000, incorporated by W. D. Logue, W. G. Pendergrass and others will develop mines near Hartman, its present daily capacity being 600 tons.

COLORADO

During the month of January Colorado mines produced 1,209,152 tons of coal. This is an increase of 221,362 tons over the production for the same month last year. The average number of men employed in and about the mines was 13,896 and average number of days worked for the month was 20.2.

INDIANA

Dr. W. N. Logan, state geologist and head of the department of economic geology at Indiana University, has been honored with a fellowship in the Royal Society of Arts, of London, England. His selection is recognition of his work in the geological field of science and research.

The Enterprise Coal and Mining Co. of Sullivan, Ind., has filed certificate of final dissolution.

ILLINOIS

Big Creek Coals, Inc., in Mine No. 3, near Harrisburg, established a record for Saline County, Feb. 14, by mining, hoisting and placing into cars 4,187 tons of coal. The previous record for Saline County was 4,162

tons mined last year at the Harco mine. January production by the Big Creek company was the largest in the company's history, though only three of the six mines worked.

The Union Colliery Co., at its Kathleen mine, near Dowell, on Feb. 15 paid the 800 men employed approximately \$95,000. The output of coal mined that fortnight, in thirteen working days, required 1,196 cars to transport it. The average of wages earned by all employees was \$123.19. The highest pay was \$194.45. Mike Maller, who led the list with 234 tons of coal, drew it.

KENTUCKY

The coal taxation bills on a tonnage basis which are now in the Kentucky General Assembly are in amounts of from 1 to 3 per cent of the sale price of the coal mined. The Nelson bill in the house was for 2½ per cent, but Mr. Nelson is willing to reduce this to 2 per cent. He figures last year's state production at about forty-three million tons, roughly valued at \$150,000,000 and figures that coal would produce about \$3,700,000 for the state in additional tax.

Fred M. Sackett, of the Byrne & Speed Coal Co., Louisville, who is affiliated with retail, jobbing and operating coal companies, has issued a statement refusing to seek nomination as U. S. Senator, but says that he would accept such an honor if tendered him by the Republican Party.

The Jones Brothers Coal Co., capital \$30,000, has been incorporated in Madisonville by F. P. Jones, T. H. Jones and others.

The Harlan-Jellico Coal Co. has been incorporated in Louisville by J. M. Dougherty, Dorothy Feil and others, with a capital of \$15,000.

The Reliance Coal & Coke Co., of Glomawr, is reported to have purchased the plant of the Defiance Coal & Coke Co., in Defiance, Ky.

The Lorena Coal Co. has been incorporated in Pineville, by D. E. Starbuck, W. R. Hughes and others.

The Willis-Harlan Coal Co., Hima, has increased its capital stock from \$40,000 to \$100,000.

MINNESOTA

The Duluth Chamber of Commerce has decided to fight the battle of the dock companies and throw the weight of its influence and the aid of its traffic department in the fight for adjustment of freight rates. At a meeting held at the Chamber the representatives of all dock companies presented their case and said that unless freight rates were changed it would mean the ruination of the companies. Plans already are under way for lessee shipments to the Head-of-the-Lakes next season.

The Superior Coal & Dock Co., is now drawn into the financial difficulties of its parent concern, the bankrupt Maynard Coal Co. The Emmons-Hawkins Hardware Co., of Huntington, W. Va., has petitioned the federal court at Duluth to administer the dock company's assets in Minnesota, complaining that the Maynard Coal Co. has failed to meet a promissory note for \$3,917 and declaring a majority of the dock company's stock is held by the Maynard Coal Co.

F. A. Wildes, State Superintendent of Mines, told the Minnesota Federation of Architectural and Engineering Societies at its annual convention held at Duluth a few weeks ago, that investigation of the fuel possibilities of the innumerable peat beds in Minnesota had reached a point "that we may confidently expect something important." Mr. Wildes spoke on "Development of Peat for Fuel Purposes." The price of this new fuel on the market, he said, must be so low that the coal operators cannot meet the competition. It will not be enough that this peat fuel can be sold for a few dollars under the present price of coal, but must be below the total actual cost of the coal without profits of any kind.

NEW JERSEY

An act has been passed by the State Senate of New Jersey providing that coal must be sold in units of 2,240 lb. to the ton instead of 2,000 lb. as at present. The bill now goes to the Assembly and then to the Governor for his action.

NEW MEXICO

The U. S. Land Office at Santa Fe has been directed by the Secretary of the Interior to offer for lease a tract of public coal land in New Mexico containing approximately 1,600 acres. The land is in the San Juan River coal field, about 12 miles northwest of Farmington. Lease for the tract will be at a government royalty of 10c. per ton for coal mined, a minimum investment in mining operations of \$100,000 during the first three years of the lease, and a minimum production of 5,000 tons of coal a year beginning with the fourth year of the lease. Lease of this land will be offered at public auction to the highest bidder and the exact date of the offering will be announced at the Santa Fe land office.

NEW YORK

Alfred D. Thompson, who has been vice president of the Titan Fuel Corporation since its organization, has resigned to assume charge of sales of the Sullivan Pocahontas Coal Sales Co., of Charleston, W. Va. This company will handle the tonnage of the Sullivan Pocahontas Co., recently formed through the consolidation of other coal companies in West Virginia, having mines in the Virginian and C. & O. railways. Mr. Thompson was formerly connected with the Pennsylvania Coal & Coke Co. and during the war was assistant deputy commissioner of the Tidewater Coal Exchange New York City.

The Central Coal & Coke Co. report for 1923 show a net income of \$565,615, equal to \$9.20 a share on the \$5,125,000 common stock of \$100 par value outstanding, after interest and provision for the preferred dividends. This compares with net income of \$309,177, or \$4.20 a share earned in 1922. The net sales amounted to \$10,472,857 against \$7,473,700 for 1922, and the surplus for the year was \$164,365 against \$61,677. The balance sheet as of Dec. 31, 1923 shows total current assets of \$3,095,246 against \$3,089,443 last year, and total current liabilities of \$2,765,208 against \$1,009,921, making net working capital \$330,038 compared with \$2,079,522 at the close of 1922. The profit and loss surplus of \$12,676,828 compares with \$13,012,047 for the year previous.

OHIO

Lee Llewellyn, formerly with the Pittsburgh Coal Washer Co., and recognized as an expert on coal preparation has been appointed general manager in charge of sales of the Houston Coal Co., of Cincinnati. Mr. Llewellyn took his B.Sc. at the University of West Virginia in 1899 and a short time later went to Pittsburgh, where he was advanced to the place of directing the designing and manufacture of coal-preparing and cleaning plants for Heyl & Patterson. He remained there for seven years and then transferred the scene of his endeavors to Alabama, where he erected cleaning plants and was for a time in active direction of operations. He returned to Pittsburgh and entered the employ of the Pittsburgh Coal Washer Co. twelve years ago. Mr. Llewellyn succeeds to the position held by the late Kuper Hood. Harry Olmstead, who has been director affairs since last fall, will become Mr. Llewellyn's assistant.

W. D. McKinney, secretary of the Southern Ohio Coal Exchange, Columbus, has been spending considerable time in Washington, D. C., appearing for that organization in the lake freight rate controversy before the I. C. C. In the complaint of the western Pennsylvania and the eastern Ohio operators asking for a revision of freight rates on lake coal, Mr. McKinney is taking a prominent part. The old question of the differential between the Ohio and the Inner Crescent fields is being revived.

C. A. Ilgenfritz has resigned as vice-president of the Stroh-Ilgenfritz Co. to become assistant purchasing agent for the Youngstown Sheet & Tube Co. Henry A. Butler will succeed Mr. Ilgenfritz as vice-president, and the name of the company will be changed to the Stroh-Butler Co. The directors, in addition to J. R. Stroh and Henry A. Butler, are: W. H. Wulf, W. E. Beadling and J. G. Butler, Jr. The Stroh-Butler Co. will continue the business

of the old company, representing producers, and dealing in coal, coke, alloys, fluorspar, steel, firebrick, fireclay and fuel oil. The change is effective March 1.

OKLAHOMA

The business of coal mining does not come under the jurisdiction of the Oklahoma State Corporation Commission, according to a ruling made by the commission. Under this opinion the commission recently dismissed the case of the Oklahoma Farmers Union Exchange vs. the Cherokee Fuel Co., of Henryetta; Consolidated Fuel Co., of Muskogee; Starr Coal Co., of Henryetta; Montezuma Creek Coal Co., of Okmulgee; Midland Coal Co., of Oklahoma City; Southwest Coal Co., of Amarillo, Texas; Superior Coal Co., of McAlester; Edwards Coal Co., of McAlester; Huges Buttery Coal Co., of McAlester, and the McAlester-Collier Coal Co., of Muskogee. C. H. Hyde, as vice president of the exchange, charged that prices of coal at the mines were "unreasonable, excessive and extortionate."

PENNSYLVANIA

Nowhere in the United States is any industry observing the child labor laws more rigidly than in the anthracite regions of Pennsylvania. Dr. Royal Meeker, Secretary of Labor and Industry, said after looking over a report of an investigation into the child labor conditions in 100 collieries in Lackawanna, Luzerne and Schuylkill counties. He asserted that the child labor evil in the anthracite field is a myth and that reports of child welfare organizations claiming that thousands of children are being illegally employed in the hard-coal mines are without foundation. The investigation was made by M. P. Frederick, an inspector of the Department of Labor and Industry who reported that he found only five boys between 14 and 16 years of age employed and that they were working in the breakers and in accordance with the existing legal requirements. Several boys under the legal age were found working with forged age certificates.

Reorganization and refinancing of the Penelec Coal Corporation, the fuel-supplying subsidiary of the Penn Public Service Corporation, is attested by a mortgage recorded in Ebensburg, Cambria County, for \$1,500,000, covering all its properties. The mortgage is dated Feb. 1, 1924, and was given by the Penelec Coal Corporation, which has a Pennsylvania charter but which maintains its principal office in New York City, to the National Bank of Commerce of New York City. The mortgage names the Penn Public Service Corporation as a third party in the agreement, based on the fact that the corporation holds a number of leases on properties included. All underlying securities of the Penelec company are retired by this action. The company owns approximately 6,000 acres of coal lands in Cambria, Indiana, Somerset, Clearfield and Centre Counties.

S. D. Warriner, president of the Lehigh Coal & Navigation Co., in his report for 1923 says that notwithstanding the miners' strike and the general observance of holidays in the anthracite fields, the production of the company was high, being exceeded only in the war years of 1917 and 1918 when working hours were abnormally increased. The income account of the company for the year ended Dec. 1923, shows net income of \$3,473,507, after expenses, charges and taxes, being equivalent to \$5.94 a share on the 584,868 shares of capital stock, compared with net of 11,587.024, or \$2.71 a share on the capital stock in the preceding year.

Eighteen acres of ground purchased by the City of Johnstown for park purposes is underlaid with three veins of coal and the only available outlets conflict with mines of the Cambria Steel plant and the Valley Smokeless Coal Co. Mayor Louis Franke recommends the selling of the coal right to the highest bidder as it would not pay the city to undertake to develop the small tract with so many obstacles in the way.

Sale of the Johnetta Brick & Coal Co., of Johnetta, to the Pittsburgh Plate Glass Company for a cash consideration of \$500,000 has been announced by J. E. Stewart, president of the Johnetta company. Included in the sale was a brick and tile plant employing 400 men and 4,200 acres of coal land.

Shelby D. Dimmick, vice-president of the Glen Alden Coal Co., Scranton, recently was elected president of the Engineers' Society of Northeastern Pennsylvania.

The Franklin Coke Co. at Tippecanoe, Fayette County, is preparing to resume

operations shipping coal after being idle for several months.

The United States Steel Corporation paid nearly \$1,500,000 to its pensioners during 1923, according to the report of the Carnegie Pension Fund. The total showed an increase of more than \$180,000 over 1922. Among pensions paid employees of the different companies were Carnegie Steel Co., Pittsburgh, \$367,469; American Steel & Wire, \$261,263; American Sheet & Tin Plate, \$196,223; National Tube, \$143,031, and H. C. Frick Coke, \$103,838. Since the fund was organized in 1911 \$9,543,235 has been paid in pensions.

UTAH

Articles of incorporation are being filed by the Consumers' Mutual Coal Co. The company will develop lands in Gordon Creek, Carbon County. Headquarters will be at Price. It is stated that the company has valuable properties which it hopes to develop to an ultimate capacity of 2,000 tons a day. The concern will be conducted along mutual lines. Organizers include Donald E. Jenkins, described as a Cincinnati and Salt Lake City capitalist, president; Arthur E. Gibson of Price, vice-president and general manager; J. Tracey Wootton, Salt Lake City attorney, secretary, and others. The treasurer is an assistant cashier of a big Salt Lake City bank.

Coal mined in Utah during January amounted to 529,570 tons compared with 468,735 for the same month last year. It was the best January output since 1920, when 589,668 tons was mined.

VIRGINIA

The New England Fuel & Transportation Co., which recently took over the Crowell & Thurlow vessels, has been reorganized as the Mystic Steamship Co., with J. R. Spear as its representative. The company is affiliated with the New England Coal & Coke Co., of which Mr. Spear also is the Norfolk representative.

The Amherst Fuel Co., of Huntington, W. Va., is contemplating locating an agency in Norfolk, but the details of the transaction have not been made public.

WASHINGTON

Coal operations may soon start on the island of Sucia, off the north of Washington coast. A government permit to prospect has been granted Henry W. Parrott, of Seattle. The island, which rises about 150 ft. at its maximum, is known to be underlaid by two coal seams, the Douglas, about 100 ft. below sea level, and the Newcastle, 200 ft. below sea level.

N. D. Moore, vice-president of the Pacific Coast Coal Co., has been elected president of the Federated Industries of Washington.

The American By-Products Corporation has filed articles of incorporation at Olympia, with a stated capital of \$2,000,000. Offices have been opened at Vancouver, with Henry C. Prudhomme in charge as secretary and general manager. Mr. Prudhomme announced that the new corporation takes over all the interests and assets of the Chemical By-Product Industries, including full ownership of all American and foreign rights to the Gordon Multiple Unit Retort and process for the recovery of oils, chemicals, drugs and other by-products from coal, lignite, oil shale, sawdust and waste wood.

WEST VIRGINIA

An injunction, the outcome of which may have an important bearing on the methods utilized in the mining of coal in West Virginia as well as in other states, is sought by the Chaplin Collieries Co. in the Circuit Court of Monongalia County to restrain the Pursglove Coal Co. from mining Pittsburgh coal underlying Sewickley coal owned by the plaintiff "in such a manner and in such a way as to unnecessarily injure the plaintiff and destroy its mine and endanger the lives of its employees," and to require the defendant to provide such supports as will protect the plaintiff in its property rights. According to parties to the suit there will be an appeal to the Supreme Court of West Virginia and perhaps to the Supreme Court of the United States without regard to the decision reached by the Circuit Court of Monongalia County. The importance of the suit lies in the fact that it will establish a rule, according to coal men, governing the mining of millions of tons of coal in West Virginia and that tracts under which there are more than one seam might be affected.

Union coal miners of southern West Virginia have formed the Pax Mining Co., capitalized at \$1,000,000 and with offices in the Boyce Building, at Charleston. The company will operate on an acreage adjacent to Grippe, on Coal River, its holdings adjoining the properties of the Brotherhood of Locomotive Engineers. Fifty-one per cent of the stock is to be owned and controlled by union miners but other union crafts or card men are to be permitted to buy stock. The president of the company is Otis Lively and its secretary and treasurer is P. R. Cameron. The company is now operating through one opening but plans twelve more openings and expects to reach a production of 2,500 tons a day within the year. Coal to be mined is in the No. 2 gas and the Big Eagle seams.

W. E. Wheeler, of the Wheeler Coal Co., of Columbus, Ohio, was in Charleston recently looking over several mines and has signed agreements to handle the output of the Big Bottom Coal Co., the Betty Ann Colliery Co. and the Lemoyne Coal Co., mines which have a daily average output of 15 cars.

J. C. Baker, of Beckley, W. Va., one of the pioneer mine managers of the Winding Gulf district, has become identified with the Newport News Coal Exchange as a field representative in the New River field. Mr. Baker will have his headquarters at Beckley.

R. R. McFall, treasurer and general manager of the Southern Fuel Co., of Morgantown, has relinquished the management of that company to become vice-president and general manager of the Universal Fuel Co., of Pittsburgh, of which H. J. Booth is president and William Booth secretary. This company operates the Riverseam Coal Co. at Hildebrand in Monongalia County.

Coal is again being shipped by the Coe-Pocahontas Coal Co., operating at Garwood in the vicinity of Clarks Gap on the Virginian Ry. The tract where the company is operating is just undergoing development and preparations are being made to erect a tippie of modern design. Among those largely interested in the Coe-Pocahontas Coal Company are the McQualls.

Six new tipples are to be erected on the properties of the Fordson Coal Co. on the Norfolk & Western Ry. in the Tug River district. The understanding is that five of the new tipples are to be constructed on the Pond Creek properties and one at Twin Branch. They are to be of steel and fully equipped with machinery for the proper preparation of coal.

The Elm Grove Mining Co., of Pittsburgh, operating in Ohio County, W. Va., has been authorized to increase its capital stock from \$2,400,000 to \$3,000,000.

CANADA

Over two million tons of Alberta coal was sold to Canadian points outside the province and the United States during 1923, states the annual report of the provincial mines branch. The total production of coal for the year was 6,866,924 tons, of which 1,382,788 tons was disposed of for consumption in Alberta, 1,937,753 for other provinces, and 83,557 tons in the United States. To the railway companies 3,110,121 tons was sold. The total production for the Alberta mines during 1923 was 890,491 tons over the total for 1922.

The announcement that Vancouver Harbour Commissioners propose the construction of coal bunkers at the Port of Vancouver to give the collieries of the Province of Alberta an opportunity to compete for the Pacific Coast mercantile business has stirred the coal operators of Alberta with enthusiasm and roused some manifestations of bitterness among the coal men of Vancouver Island. The managements of northern Alberta collieries already are organizing so as to be in a position to take full advantage of the new outlet when the time comes. Meanwhile William Sloan, Minister of Mines, and the representatives in the Provincial Legislature of the City of Nanaimo have obtained from the Harbor Commissioners the assurance that the bunkers to be built are not intended for the sole use of Alberta coals but will be open also to handle the coals of the island and other parts of the province. An interesting sidelight on the situation developed when the Home Products Association of Vancouver asked the Nanaimo Board of Trade to indorse the principle of the consumption of home products in preference to those imported. The Nanaimo organization wanted to know where the Vancouver association stood in the matter of encouragement of outside competition with locally produced coal.

New Equipment

Approved Single-Stage Fire Pump

Centrifugal pumps have been used for fire-protection purposes for many years and until recently those recommended by the underwriters were of 500, 750, 1,000 and 1,500 gallons per

Fig. 1—Fittings for Centrifugal-Type Fire Pump

For control and test of the fire lines a set of fittings such as shown here is highly necessary. Pressure gages show the pressure required to deliver different volumes of water through the various fire lines.

minute capacity suitable for operation at a pressure of 100 lb. gage. Originally these pumps were made in the multistage type and ran at 1,150 r.p.m.; later the specifications were changed to permit the use of multistage 1,800-

r.p.m. pumps, and recently the specifications have been changed to permit the use of single-stage pumps.

In line with these changes the Allis-Chalmers Mfg. Co. is now building a single-stage fire pump in accordance with the above specifications. The new pump is a development of one of this company's popular single-stage pumps which it is claimed has operated successfully against heads as high as 300 ft.

Auxiliary Relay for Long Time-Limit Service

For the purpose of controlling switching operations, mechanical operations and processes where a long time limit is desired, a relay, known as the type GK auxiliary relay, has been developed by the Westinghouse Electric & Mfg. Co. Extensive use has been made of this relay in automatic substations where various operations must be timed.

The relay is distinctive in that it is self contained and is so enclosed in a dust-proof case that it can be mounted wherever desired. The timing is accurate, yet the device is designed so that it can be adjusted by any careful workman. The possible time limit adjustments range from a maximum of 40 minutes to a minimum of 3 minutes.

The operation is effected by a train of gears and worms driven by a standard fan-type motor. The last shaft in the train which carries the contacts is operated by a worm which is so arranged that it is normally disengaged by a spring. This worm is mounted on a trunnion and is connected to a small electro-magnet which when energized will engage the worm with the gear.

Long Time-Limit Relay

This relay is arranged for time delays varying from 3 minutes to 40 minutes.

This coil usually is connected in parallel with the motor winding so that as soon as the relay is energized the motor is started and the coil energized. The worm then engages and the contact starts to move.

Healing Mule Collar

The Thomson Co., of Fitchburg, Mass., has just announced a new and improved zinc mule collar for mine mules. The hook formerly at the top is not needed in mine service and therefore has been eliminated. A guard has been substituted at the top, so that the collar will be perfectly smooth and prevent catching in mine timbers, ropes, guides, etc.

These collars are much lighter than the usual leather collars and being made of zinc form a zinc oxide protecting and healing surface which assists in the cure of any neck or shoulder sores with which the mule may be suffering. The collars are easily cleaned, thus rendering the collection of germs unlikely. Special springs cushion the shock when starting a load or when the car strikes an obstruction.

Fig. 2—Single-Stage Fire Pump

Due to the heavy construction of this pump it has been possible to operate it safely on heads ranging as high as 300 ft. The company has been very successful in the manufacture of pumping units because the complete outfit, including the motor, is made in the one factory, thus insuring perfect design and alignment.

Improved Zinc Collar

For mine mules this collar has been made as plain as possible so as to prevent catching into any obstructions along the road.

Number 10

We and They

INVOLVED in the oil scandal are many men who have been foremost in condemning the coal-mining industry. It was McAdoo who believed that the coal men profited unduly, and loudly did he proclaim it. It appears that the price may be too high for coal but cannot be too high for influence at the capital. Someone has well said that "McAdoo would sooner be in right than President." It was Palmer and Daugherty also who lamented the lack of patriotism of mine operators. These government officials, past and present, may be suffering from undue public suspicion, and the coal man, himself too often suspected with little reason, will do well to treat these men with a caution in judgment and a temperance in statement that Palmer and Daugherty too often have failed to evidence.

A Job of Gloom

ONLY a few years ago our thick-walled factories with their small windows were places of dust and dirt, where men worked under a considerable handicap. Did they want to see anything clearly they took it to a window—an open window, the dirt on the windows hiding the sun rays—or to an open door. Now we have larger windows and at night bright lights. Everything can be inspected anywhere in the building. By night or day work goes on unimpeded by gloom, and manufacturers have found that light has paid dividends.

The mines alone have continued dark. They have with few exceptions relied on the uncertain light of cap and hand lamps—in this country principally the former, in Europe mostly the latter. Surely the time is coming when the practice at some mines of illuminating face as well as roadways will be standard.

In the present glutted state of the market clean coal is needed. Theoretically, the operator weighs the coal and refuse that the miner loads, throws away the refuse and pays the miner for all he sends out. As a matter of fact at some mines he probably docks those sending particularly bad coal so heavily that he comes more nearly even when he compares his railroad with his mine-car rates.

However, it is not just to distribute all the cleaning burden on the evil doer and in some cases the loss falls largely, if not entirely, on the operator. In consequence he will do well to give the mine worker of honest intentions a good light whereby to clean his coal. He may save considerable losses at the tippie by so doing. The greater light will cause less material to be wasted, will make it easier to watch the roof, will speed up the work and will make the miner more cheery and less discontented.

Mining is gloomy work at best. A little light at the faces will brighten the day's toil. In the roadways when the men watch the roof for low wires and timbers, they frequently fall by stumbling over coal and slate, upstanding ties and traversing rails. Similarly

when they watch the floor they strike their heads against wire and timbers. A light in the roadway will prevent such accidents which are serious, especially where locomotives are about to run down the fallen man—a trip rider, for instance.

Ten years from now, we shall be wondering, as we look back, that in these days we were contented to light our mines with only the meager light of cap lamps. The change suggested is not a large one, no larger than the change in factory illumination in the past few years.

Light Is Light

NO MATTER the source of advice, if it is good, it is well to heed it. The Coal Commission was in many matters not fair, but this at least is true of it: It expressed the public mind, and after all, it is the reactions of the public that the coal operator has to meet and appease. Let us regard its pronouncements, therefore, as revelations of the popular appraisal of the coal industry and, not seeking in anger to meet its false judgment, endeavor to find a way to merit popular approbation.

The fact is the coal industry is not properly "sold" to the American public. The coal man has argued in heat and passion and not with due calmness. The man who is upset and indignant in making rebuttal is usually not prudent or convincing. He in general only involves himself in his argument.

His better plan is to ask questions and put the public on its defense with a "How?" and a "Why?" The average man thus confronted, asked to give an answer, usually ends by giving convincing evidence that he does not know or appreciate what he has been saying. At least this is gained from the report of the Commission: that every one concedes that it had no solution, had no "How" and no "Why" to give the consumer, the coal man or the mine worker. Where no one can provide a remedy, the public must needs be patient.

What is said about the main part of the report should be modified, because some of its parts, especially the engineering report, was written by efficiency engineers aided by mining men. Unfavorable to our mining practice as it is, it does not err in the direction of excessive censure. Good mines were picked out deliberately for investigation, yet the findings were sufficiently distressing. Fortunately, they were made just at the time when instrumentalities were coming into being that may profoundly modify the inefficiencies described.

There is hope, bright hope, that a few years hence the miner will lose no time at the face, the trips will not stand at the parting and the daymen will not idle at the tippie. The engineering report does not say much about the cure. Like much work by efficiency engineers it relies on co-ordination and co-operation to end evils that only mechanical engineering adequately can remove and that management can merely improve. The conveyor that has revolutionized many industries

is on hand to reconstruct ours. Badly is this tool of industry needed, for the mechanical loader has completely broken down our already faulty transportation system.

The failures to get the anticipated tonnages from mechanical loaders are convincing evidence that the Commission's strictures on irregular mine-car service are justified, and the only way to make loaders do a good day's work with broken roof behind the loading machines is to have a conveyor to remove the coal to some place with an unbroken roof, where cars can be filled steadily. Where several mechanical loaders are used, the only way to prevent the congestion inevitably consequent on the use of several conveyors feeding to several trips is to have an aggregating conveyor receiving from several gathering conveyors and feeding to a single trip or carrying the coal direct to the tippie.

The main Coal Commission report has told what the public thinks. The engineer's portion of it has revealed the glaring inefficiencies that exist underground. Light is light, even if it comes from a commission of which a few at least were men who could not run a mine themselves were they given it without any debt or other encumbrance.

The Commission may have feared to tell the whole truth about the unions, may have palliated what cannot be excused or forgiven, but it told us some matters we would do well to take to heart. Though good counsel was marred often by bad logic, many a true word slipped in and a poor plan it would be to let the evil overshadow the good.

Prices and the Wage Contract

REMARKABLE and almost impossible to forecast has been the trend of recent events in the bituminous-coal industry. It was thought that the western Pennsylvania coal operators would not appear in Jacksonville to negotiate a settlement, but pressure from President Coolidge and Herbert Hoover brought them there.

It seemed almost incredible that with business being lost almost beyond recovery by reason of a high wage scale the operators would consent to sign for the present wage, even though the irresistible though more indirect logic of the situation pointed that way. But sign they did.

Indications pointed to a long fight on the period of contract. But even there again the needle pointed in the wrong direction. The contract was signed for the three years, the miners wanting a four-year contract, and many—perhaps most—of the operators wanting to sign for a single year.

Now that the wage scale has been approved for a period of three years by the subcommittee of miners and operators the public will be wondering what effect the settlement will have on the price of coal. That is a natural question but one not easily answered. The settlement will result in a glutted market for coal, and lower prices might be expected as a result if they had not already attained the irreducible minimum for the present union wage scale. The losses incurred by the operators of union bituminous-coal mines are rapidly drawing them into bankruptcy.

However, the price may be somewhat higher rather than lower. Contracts for coal delivery are lapsing. It was well known that these contracts were all that enabled some operators to keep going. When they come

to an end the mines that relied on them will have to suspend or get a higher price for spot coal. That will tend to stiffen the market. The removal of the weaker brethren will make it possible for those who remain in the field to ask for their coal something a little nearer cost, enough in short to make it more profitable to face the losses of operation in preference to the greater losses of shutdown in an industry where shutdowns are extremely expensive. That hope may be blasted by the low prices of a non-union field ready to cut wages to any figure that will keep its mines running.

Those who close their mines will do so for a long time. They will disband their forces, board up their houses and in some cases let their mines flood if they are shallow and relatively easily drained. It will be clear to them that only a measurable increase in price will make it worth while to undertake the high costs of resumption. In fact their finances during the interim becoming more involved may prevent them from resuming. The low-cost mines, therefore, will get the benefit of the business of those operations which cannot continue to work.

Another element in the situation may enter, however, to get the public cheaper coal—the conveyor and the mechanical loader. The prospect of cheap coal for a long period will force more economical methods of production. It will be recognized that cheaper operation and better preparation will be the only way to keep in the market. The miners will be amenable in view of the financial stress and they will not oppose complete mechanization of the mines. This will have its effect in reducing price. So after all is said it is difficult to forecast the ups and downs of the index of prices, swayed as it is by many adverse influences of an imponderable character.

Safety a Major Consideration

ONE of the first thoughts when business gets unprofitable is to cut off all indirect expenditures—those which do not produce immediate profit. Expenditures on safety are among these, but the cost of running risks is too heavy to make such economies profitable and savings of this kind are certainly not moral.

In fact, at no time is safety more neglected by the mine workers and foremen than during a time of low profits. The miner anxious to make a big day during an unsteady run fails to put up a prop if thereby he can the more promptly fill a car. The motorman and his trip rider, harried to transport a large tonnage and so cut the cost of haulage, run risks in coupling cars, in opening doors and in taking switches. The foreman seeks to reduce costs by bringing pressure to bear on those who would report places for gas. He seeks to have all his men engaged in directly profitable labor and not at work that, as he would put it, merely assures safety.

At such times it is more than ever necessary to remember the cost of physical hazard and to have safety men around the works whose whole standing with the company lies not in the cheapness of coal but in the freedom from accident. Every day's coal should be charged with the accident costs of operating the mine so that the hazard always would be remembered as part of the cost to be lowered. Accidents are not unavoidable charges in mining. They are costs which good management will much reduce, and to overlook them is to involve the mine in difficulties sooner or later.

BY ALPHONSE F. BROSKY

Assistant Editor, *Coal Age*

FEW operations in the East utilize alternating capacity for all purposes other than haulage. The Lewis mine of the Hudson Coal Co., located at Wolf Summit, W. Va., is one of these. As a result the electrical system employed at this mine is well worthy of careful consideration.

Adoption of alternating current forestalls many of the troubles to which direct-current equipment is subject. At the present time, however, this mine is not developed so extensively that appreciable line losses would be incurred if direct current were employed. Consequently no necessity at present would exist for an excessive yardage of copper feed cable. The officials of this company are, however, anticipating the future needs of this development and providing for the time when the workings will be sufficiently extended to warrant the use of another underground substation, one already having been installed. When such time shall arrive the foresight of the officials who have recommended the present use of alternating current will become apparent.

Briefly, future plans call for the stepping down of a

NOTE—Headpiece shows the tippie of Lewis Mine of the Hudson Coal Co. Because circular picking tables are used the building is more nearly square than most structures of this kind. A belt conveyor brings the coal from the underground workings to the preparator.

22,000-volt incoming line potential in a bank of transformers to be located near the tippie. These will reduce the voltage to 2,200. Branch lines carrying this potential will radiate from the primary transformers to various points on the property, where they will enter the underground workings through boreholes. At these various points, underground transformer stations will be installed to feed the direct-current haulage lines.

Several precautionary measures have been taken at this operation to obviate possible shutdowns, either momentary or prolonged, as well as to surmount the difficulties entailed by fluctuating line voltage. Such measures call for the exercise of considerable study and ingenuity in order to adapt them to the requirements of any particular plant. J. P. Rosier, the electrical adviser at this installation, has solved the difficulties with which he was confronted in a manner that invites the adoption of similar plans at other developments.

ALL EQUIPMENT NOW USES 440 VOLTS

In the present alternating-current system an incoming potential of 22,000 volts is stepped down to 440 volts by means of a bank of three 50-kva. transformers in a surface station near the tippie. Incidentally, this will become the primary transformer station, when proposed extensions and alterations to the system are

made. All equipment now installed, both on the surface and below ground, is rated at 440 volts. At the present time the main conductors are taken down the airshaft to the underground distribution circuit. In order to protect the 440-volt lines and the equipment connected to them from single-phasing and line burn-outs, which might result from falls of roof or from other causes, an alternating-current breaker is employed.

A single-phase and reverse-current relay operates in series with the fan circuit, so that single- or reverse-phasing in the high-tension incoming lines results in shutting down the 50-hp. induction motor, by which the 5-ft. reversible centrifugal fan is driven. This relay automatically opens the main-line alternating-current circuit breaker and holds it open until such time as the phasing difficulty is corrected, after which the breaker closes automatically. The fan must, however, be restarted by hand.

Within the mine the alternating-current lines of 4/0 bare copper are strung on glass insulators fastened to the ribs of the entries. Where these lines cross haulage roads and manways they are suitably protected.

Interruptions to power supply and the burning out of the ventilating-fan motor are imminent causes of worry to the mine manager if he is not prepared to meet such emergencies. Steam, gasoline or oil engines are in many cases installed as stand-bys to provide against such contingencies. The Hudson Coal Co., however, has employed a different type of auxiliary equipment in the form of a 20-hp. direct-current motor that can be driven from the storage battery of a gathering locomotive in the event of a lasting power interruption or from a motor-generator in the underground substation in case the main fan motor should burn out.

This auxiliary direct-current motor is installed directly below the fan pulley, as may be seen in one of the accompanying illustrations. It is provided with a tension or belt tightener in addition to the drive pulley on the motor shaft. This tension may be adjusted by means of a take-up and compression spring, which facilitates a quick adjustment of the driving belt between the auxiliary motor and the fan.

A lead-armored, jute-covered cable extends from this direct-current motor down the air shaft to a bare 2/0 conductor leading to the main switchboard in the

Fig. 2—A.C. Circuit Breaker and Out-of-Phase Relay

The upper cabinet contains the relay which automatically opens the circuit breaker and holds it open until the phasing difficulty has been eliminated. The breaker then closes automatically.

underground substation. Through this switchboard, connections may be made with a 60-kw. 125-volt motor-generator set. This connection will be used in case the regular alternating-current fan motor should fail.

Furthermore, a connection may be made to the storage battery of a 6-ton gathering locomotive in the motor barn should power fail on the incoming line. The capacity of the storage battery on the locomotive is 440 amp.hr., which is sufficient to drive the fan for about 5 hr. at half speed, or 125 r.p.m. When operating at this rate the fan will generate about 50,000 cu.ft. of air per minute.

In addition to the motor-generator set already mentioned, the present underground substation houses a 100-kw., 275-volt, 150-kva. synchronous motor-generator for correcting the power factor. This latter machine is of the three-wire type and is used for charging storage batteries and for supplying direct current to the trolley lines. Should an accident befall this motor-generator set, the 125-volt motor-generator can be switched to the trolley line and one of the storage-battery gathering locomotives can draw power for operation as a main-line trolley machine. This particular locomotive is specially wired and equipped to meet this requirement.

Proper balancing of equipment and the application, in new combinations of principles already known, will confine periods of shutdown to the time required to change over from one source of power to another. There can be little doubt that broader co-ordination of electrical lines and equipment can be so executed as to serve other similar purposes.

MOST OF THE COAL RECOVERED ON SECOND MINING

It is the firm belief of this coal company that in first mining not more than 10 to 15 per cent of the ultimate recovery should be removed from any room section where the roof is tender and falls readily. As a result, the block system of mining, the general layout of which differs but little from that originated in the Fairmont field and used successfully elsewhere, has been chosen. A system of operation was sought for this mine that would incorporate narrow rooms and wide pillars, as these pillars were expected to stand for a long period with a minimum of timbering. It was necessary also that the pillars should be of such dimensions that

Fig. 1—Motor-Generator Sets Underground

One of these units furnishes direct current at 275 volts to the trolley lines; the other furnishes 125 volt direct current for battery charging, for operation of the standby fan motor and for operation of a storage battery and trolley locomotive when the main haulage unit fails.

they might be split, slabbed or split again to form wing pillars.

It was the conviction of the officials of the Hudson Coal Co., that flexibility in the recovery of big pillars would eliminate some of the dangers usually encountered in retreat working and make possible the mining of gob-encroached pillars that otherwise might be lost. Furthermore, the system adopted possesses an additional advantage, in that it permits pillar blocks to be mined if desired by some modification of longwall method in conjunction with mechanical loaders and conveyors. No other system could be found that would meet the present and future needs of the Lewis mine, and as a consequence, no other recourse remained but to adopt the block system of room-and-pillar working, which in reality is only a modification of the almost universal system in vogue throughout this country.

Coal is mined by the block system in several other operations in the Fairmont field, and at Fleming, Ky., the Elkhorn Coal Corporation is operating in this way in the thick Elkhorn bed under the typically heavy cover of the Kentucky mountains, an exceptionally high recovery being attained. I mention these instances of the successful utilization of this system to substantiate its practicability and to refute various rumors that have received circulation recently and that tend to foster a contrary belief.

In some cases this system has been unsuccessful and much coal has been lost, not only by isolation of stumps and larger portions of blocks in the goaf, but by the squeezing as the result of negligence of large areas already laid out in blocks. The prime principles governing successful mining by rooms and block pillars are no different from those that must be observed in all other working-place layouts.

These are, (1) that no pillars must be allowed to lag behind the line or front of retreat; (2) that every body of coal, large or small, lost in the gob adds to the difficulty of controlling the roof and, (3) that every precaution must be taken to make the roof break as near as possible to the retreating pillars. Officials of both the Elkhorn Coal Corporation and the Hudson Coal Co., believe that success with this system throughout long periods of time and with little or no reduction in recovery is dependent on the ability of the mine foreman to make his daily advances regularly and systematically.

The Lewis mine operates in the Pittsburgh seam which has an average thickness at this point of 7 ft. It is located in a tract of 1,034 acres. At the tippie, which is located at the northwestern corner of the property, the thickness of cover slightly exceeds 50 ft. Consequently, as mentioned in *Coal Age* of Dec. 20, 1923, p. 919, the coal is brought to the surface by a belt conveyor 247 ft. long center to center and installed on an inclination of 18 deg. The main heading is driven southward from the slope bottom on the strike of the coal and incidentally in close proximity to the western boundary of the property. Five entries have been thus driven. One is employed for haulage, one as a manway and three as air courses. Two of these passages are intakes and three are returns. They are driven 10 ft. wide on 40-ft. centers and are protected by barrier pillars 400 ft. wide.

Face headings on 350-ft. centers are driven eastward to the rise at an angle of 72 deg. to the main headings. Rooms are driven parallel to the main heading on 90-ft. centers and the pillars between them are

subdivided into 80-ft. blocks by crosscuts on 90-ft. centers, these crosscuts being driven parallel to the face headings. The relative directions of headings and crosscuts with regard to the faces and butts of the coal have been fixed as described for the reason that the major part of the tight working in the blocks is against the faces. Rooms are made 12 ft. wide. The layout differs from the block system as usually employed, in that crosscuts are driven in adjacent room pillars in such a way as to stagger the pillar blocks. By this means, the roof is not greatly weakened at the corners of the blocks.

PILLAR COAL IS EASILY RECOVERED

The pillar coal is easily recovered by splitting a block in two and by pulling the wing pillars from crosscuts in each half of the block. It is needless to go into further details, for the methods of attack of necessity vary with the conditions encountered. Most of the tight work is facilitated by top cutting with arcwall machines, so that, in shooting, the roof is not disturbed.

Rooms and pillar blocks are at present developed in an area of about 125 acres, of which only a small portion has been completely mined. A pillar section off No. 2 heading and one off No. 6 heading yield most of the present output, amounting to 1,500 tons daily. Another section is being started off No. 9 heading, in compliance with the development plan which calls for an ultimate daily capacity of about 3,000 tons. Gob lines are maintained at an angle of about 45 deg. to the heading. Where they meet, they will form an angle of 90 deg. Eventually, when these three sections are

Fig. 3—Standby Motor for the Fan

This d.c. motor, installed with its pulley directly under the fan pulley, may draw current either from the 125 volt motor-generator set in the underground substation or from the storage battery of a gathering locomotive in the motor barn.

FIG. 4

Main Heading

Because the bottom in this mine swells excessively under the action of moisture the ties are here so closely spaced as to almost floor the track. Drainage ditches also must be kept open religiously. Both the ribs of this heading and the steel roof beams fitted with lagging have been white-washed thus greatly aiding in the illumination. Abundant light at points such as this is a great aid to accident prevention.

connected through the goaf the continuous line thus formed will be in the shape of saw teeth.

Some engineers hold that additional roof trouble is encountered at the point where gob lines of two approaching pillar sections meet in the manner above described. No doubt this is true to a certain extent, but difficulty of this kind so far experienced has not been sufficiently great to induce those who have adopted this plan to alter it. No unusual roof trouble is apparent in either of the two approaching pillar sections, and it is hardly probable that much coal will be lost at the point where the two sections meet.

The junction angle between the gob lines, however, should not be less than 90 deg. The early attainment of capacity production necessitates such a procedure, otherwise a sufficient number of working places would not be available. Advocates of the saw-tooth gob line assert that the loss of coal in the trough of these teeth is not excessive. Although these points have not yet been created in the Lewis mine, the management does not anticipate any serious difficulty when the gob lines close.

The conditions prevalent in this mine are almost ideal for the use of storage-battery locomotives for gathering. This is because the main heading is on the strike of the coal, which dips only sufficiently to establish a natural grade of about 1 per cent in favor of the loads on the cross-headings. It should be recalled, also, that practically all the coal lies east of the main heading.

Five 6-ton storage-battery locomotives gather the coal and deliver it to the main sidetrack located 2,000 ft. from the slope bottom. From this sidetrack the entire output, totaling at present 1,500 tons per day, is hauled to the rotary dump at the foot of the slope by an 8-ton duplex trolley and storage-battery locomotive. Inasmuch as this latter machine is equipped with two motors, one drawing its energy from storage batteries and the other taking current from the trolley wire, it is prepared to assist in gathering when not engaged in haulage.

The wisdom of this choice of equipment is imme-

diately apparent. All five gathering locomotives are kept busy throughout the shift, each serving about twenty working places and gathering 300 tons of coal and hauling it a distance of approximately 1,800 ft. to the main sidetrack. The provision of a storage battery on the main-line haulage locomotive renders this machine a self-contained unit capable of traveling anywhere in the mine regardless of whether the track is trolleyed and bonded or otherwise. It thus adds greatly to the flexibility of the haulage system and to the utility of the machine itself.

ROMANS BURNED BRITISH COAL.—Excavation has proved beyond all doubt that coal was used by the Romans; ashes and stores of the unburnt mineral are being found all along the Wall, at Lanchester and Ebchester, in Durham, at Wroxeter, in Shropshire, and elsewhere. [The Wall to which reference is made is the Roman wall between the Tyne, near Newcastle, and the Solway on the western coast.] For the most part, it appears to have been used for working iron, but it was possibly also used for heating hypocausts [furnaces which heated the floors of Roman bathhouses]. There seems good reason to believe that it formed the fuel of the sacred fire in the temple of Minerva at Bath, as Solinus, writing about the end of the third century, comments on the "stony balls" which were left as ashes by this sacred fire. That such coal as was used by the Romans was obtained from outcrops, where the seams came to the surface is more than probable. There appears to be no certain evidence of any regular mining for coal at this period.—*English Industries in the Middle Ages*, by L. F. Salzman.

W. W. ODELL, fuel engineer, U. S. Bureau of Mines, has commenced the study of peat as a fuel, and is spending some time at the Minneapolis experiment station of the bureau, in the northern peat district. So far he has made preliminary studies as to the best methods of attacking the problem with the funds available.

How the Modern Underfeed Stoker Works, and Why*

Number of Underfeed Stokers Has Increased Rapidly—What Special Features in Design Have Been Introduced for Burning Western Coals—Progress of Ash in Fire Must Be Given Serious Consideration

BY JOSEPH G. WORKER†

IN ANY study of fuel-burning equipment, we must discriminate between theory and good practical operating engineering. Our problem in fuel burning is not entirely one of selecting the most efficient thermal system. We must consider also those physical factors in the fuel bed which vitally affect its combustion and determine its ultimate efficiency.

Low flue-gas temperatures, preheated air, hollow-wall construction, etc., affect the overall efficiency of a combustion system from five to ten per cent, but they are not a part of any one particular combustion system, although they may be provided with any one of them. In our endeavor to find any given condition which will give the best results from a dollar-and-cents basis great care must be taken to see that the results obtained are not attributed to the wrong causes.

The mechanical stoker, more than any other piece of boiler-room equipment, has made it possible to design boiler plants of the present high capacity, to burn

were equipped with one type or other of underfeed stoker, about 200,000 hp. were provided with some type of chain-grate stoker and about 50,000 hp. with some kind of overfeed stoker. That is, about 75 per cent of the stokers sold in the United States during the year 1922 were of the underfeed type.

Though these figures throw some light on our subject, they are perhaps as expressive of economic conditions as they are of efficiencies in the different combustion systems. These figures may be surprising, because only a few years ago any of us would have correctly stated that most of the stokers sold in the West were of the chain-grate type. The change has come about slowly. It may have been delayed at times, but we are now at the point where almost as many underfeed stokers are being installed in the West as in the East.

CONFUSE FUEL BURNING WITH CLEANING

We may have been correct in the past in claiming that no stoker handles all grades of coal with the same degree of satisfaction. In that thought, however, we allowed ourselves to consider difficulties in mechanical operation that were in no way a part of the fuel-burning system, but were to a large extent a part of the cleaning process of the fuel bed.

There have always been two types of stoker designers. One had tendencies toward building a machine that would offer the best combustion possibilities, irrespective of the cleaning devices. Others mixed and confused the problem, with the result that stokers have been designed which, though they were not the most efficient in the burning of coal, handled clinkers so satisfactorily that their lack of combustion efficiency was willingly overlooked.

We have heard many times that the underfeed was all right for Middle-west coals, except that when it was used the clinkers gave too much trouble. In many

Fig. 1—Fuel Bodies of an Underfeed Fire Bed

During the coking process, the coal swells and forms arches over the tuyeres. The incandescent fuel is on the top and the coking area extends back into the retorts.

the fuel efficiently and rapidly and to obtain as much as 6 kw. of generator capacity per boiler horsepower. Only fifteen years ago, we were obliged to install a boiler horsepower for every 2 kw. generated.

Many types of stokers have assisted in this development. The underfeed stoker has played its part and has figured prominently in this progress. To appreciate the extent to which it is now used to burn Middle-west coals, a survey was made and the following facts were revealed:

A little over 1,000,000 hp. of boilers were sold in the United States during the year 1922, by twenty-eight boiler companies. This includes about 800,000 hp. of all types of mechanical stokers. Of these, 550,000 hp.

Fig. 2—Taylor Underfeed Fuel Bed

This illustration shows the gravity ash feed. The fine ash floats on the top of the fuel bed and slowly works its way down into the ashpit.

*Abstract of address delivered at Chicago Section, American Society of Mechanical Engineers, Jan. 15.

†President, Stoker Manufacturers' Association.

Fig. 3—Section Through Fire Bed

instances those who made this statement failed to investigate how this difficulty could be overcome without disturbing the primary combustion system.

Years ago, when the underfeed principle was being developed, some of the power stations of the East had a somewhat similar experience. Some people could not see its virtues, and almost endless discussion resulted. Improvements were made on one part or other of the controlling mechanism, but the underfeed method of burning coal was, probably more than any other single element, the reason for the success of the whole system.

Many new stoker developments were started in the West, but rarely were their problems finally and definitely worked out. If they were, it was when some other part of the country took up the problem. Even then, as the coal conditions in that section were not so severe as in the West, the solution of the difficulty gave such an impetus to the stoker business that no further effort or money was spent in modifying a particular stoker to suit Western coals.

It is important to obtain a clear idea of the principles involved in the burning of a fuel bed on a multiple-retort underfeed stoker. An endeavor has been made to exemplify in Fig. 1 some of the ideas of Elwood Taylor, by whom this type of stoker was invented. The inventor's claim, when he petitioned for patents on this device, explains clearly the movement of the fuel.

UNDERFEED FUEL BED IS NOT AGITATED

Many have the idea that an underfeed fuel bed is agitated and that the fuel is pushed across the supporting structure from the point where it enters the fuel bed to the point where it is discharged as ash; but the inventor stated that in the operation of his stoker, the fuel bodies in the several retorts constituted the legs of a single fuel bed. This bed burned with the incandescent fuel on top and with the coking fuel underneath extending back into the retorts.

Owing to the cohesion and arching properties of the fuel as it swells during the coking process, the fuel bed receives its support from the walls of the retort and is fed outwardly by the retort pushers.

It arches over the tuyere faces and so is kept substantially free from them as shown in the sketch. This illustration also plainly shows the partially coked coal extending into the retorts, an endeavor being made to make plain the way in which the coke arches over the tuyeres. This operating principle and the claim of the inventor has been demonstrated in research work in connection with this stoker. It has also been substantiated by expert engineering testimony.

COKE ARCHES HOLD UP FUEL BED

Few have realized that the coke arches in the underfeed stoker act in the combustion process as the refractory arches do in the chain-grate and other stokers. These underfeed arches are made up of partially burned coal and are continuously being burned up and reformed. Immediately over these arches of partially burned coal is the incandescent and major fuel bed extending across the openings of the retorts.

Finally, it will be noted that the fine ash floats on top of the entire fuel bed, Fig. 2. These particles of ash are small and were originally independent pieces of green fuel. The ash is fed by gravity down the slope of the fuel bed, the movement being induced by the periodical introduction of cartridges of fuel which give a weaving movement to the fuel bed and an outward feed movement across the mouth of the retort.

Often the idea is advanced that the agitation of underfeed fuel beds is undesirable where a high-ash coal is used. A careful analysis of these fuel beds will show, in fact, that the fuel is not agitated or mixed as is generally supposed. The injection of these cartridges of fuel is so slow that the movement at the time the coal is introduced is hardly perceptible to the eye. The arching of the fuel in the retort relieves the pressure on the coal pushers when they retreat for another charge, and consequently the fuel movement is always outward.

ASH ROLLS DOWN SLOPE BY GRAVITY

The operation of the underfeed stoker is thus easily distinguishable from that of forms of mechanical stokers employing inclined grates in which the green fuel is fed by the overfeed principle. No grate or fuel support, such as is employed by overfeed or chain-grate stokers, is used in the underfeed types, the fuel instead being supported from the retorts. This is made clear by Fig. 3, in which all the supporting structure of an underfeed fuel bed has been taken away. This shows how the underfeed fire is supported on legs of coal and the major weight of the fuel bed is transmitted to the retorts.

The formation and progress of the ash of an underfeed fuel bed is generally misunderstood. No pushers or rams compel the ash in an underfeed fuel bed to progress through the fire. It can be proved that the

Fig. 4—Formation of Clinker on Side Wall

Unless the ash continues to flow in its natural course a clinker quickly builds up and grows larger until removed.

Fig. 5—Rotary Ash Discharger Which Prevents Formation of Clinker

This is one of the latest devices adapted to stokers. The illustration shows a series of air backs and water backs frequently used on the front face of the bridge wall to prevent stoppage of the ash in its course to the clinker grinder. Clinkering coal no longer presents serious difficulties to stoker manufacturers.

feed of green fuel induces the ash to move by gravity down the slope of the fuel bed. A close-up view of the surface of such a bed would show clearly that the fine particles of ash travel down the incline. The inclination of the fuel bed must be such that the ash will move in this manner.

Having developed the principles of a proper fuel-burning process, have we given enough thought to the machinery necessary to allow a fuel bed to function according to its principles? If there were no side walls nor bridge walls or other refractory parts surrounding an underfeed stoker, and nothing to retard the flow of ash from the top of the fuel bed to the bottom, would clinkers form?

A particle of ash in a fuel bed, as shown in Fig. 4, if stopped in its proper course down the slope adheres to the side wall and backs up the oncoming ash, thus commencing the formation of clinker. Unless it is started on its course again, it will gradually grow until it builds out underneath the fuel bed and in some cases down into the retorts.

In developing the furnace construction for underfeed stokers, side-wall air plates, air-cooled crusher plates, water backs, etc., have been devised and constructed, all for the purpose of keeping the ash from stopping in its course down the fuel bed. Side-wall air backs are now quite generally used with underfeed stokers. These plates are working quite satisfactorily and, of course, are much better than the refractory material which they have replaced.

ASHES STOPPED AT BRIDGE WALL AND CLINKERED

If we assume that the ash is not stopped in its descent of the slope of the fuel bed, it will eventually reach the bridge wall. When multiple-retort underfeed stokers were first installed they were equipped with dump grates, and unless this part of the stoker was handled properly, the ashes would stop at the bridge wall and gradually accumulate and back up so that large clinkers would form. These would not only lie on the dump grates but would build up into the fuel bed.

Without disturbing the principles of this fuel bed, the designers tackled the problem of the stoppage and clinkering at the bridge wall and the result was what is commonly termed the rotary-ash discharger shown in Fig. 5. This device is necessary for the continuous

progress of the ash and clinker from underfeed-stoker fires.

It is obvious that under certain conditions of operation, it would not be necessary to actuate continuously the crusher in the ash well. It is therefore only operated to keep in tune with the formation of ash as it proceeds down the slope of the fuel bed. Air backs and water backs are used on the front face of the bridge wall to prevent the ash or clinker from being stopped in its downward course through the ash wells and through the crusher rolls into the ash pit.

The West is now solving some of these clinker problems. No longer are we in fear of what the ash in the coal may do. At least, the clinkering of Western coals is no longer allowed to hinder good engineering progress.

Mechanizing French Coal Mines

In order to meet the increased cost of operation, French coal-mining companies have given special attention to mechanical equipment suited to the conditions in French mines. This has resulted in the increase in the percentage of coal produced by machines in one district from 4.27 per cent in 1913 to 16 per cent in 1922, says Chester Lloyd Jones, Commercial Attache, Paris, in a report to the Department of Commerce.

The character of the deposits is such that certain types of coal mining machinery as used in the United States will not always work with efficiency. Nevertheless in the Pas-de-Calais and in the Nord marked advance has been made in recent years. In the Pas-de-Calais there are two American machines of special type and one bar coal cutter in use or under trial. The most successful type employed is that of the mechanical pick-hammer. Of these there were in use in 1911 only 743, in 1913, 1,392; but in 1922, 2,872 were employed. Perforating hammers of the hand type have also become prominent, the number in use having risen from 1,878 in 1913 to 2,343 in 1922.

In the Nord the coal mined by mechanical means before the war was about 2.5 per cent of the total, but in 1922 this had increased to 10 per cent. Six coal cutting machines were operated during the year, but, because of the nature of the coal deposits, they showed a yield of only some 17,000 tons.

Just How Harmful Is Dust?

Coal Miners Not Immune from Tuberculosis According to Insurance Statistics—No Physiological Trouble from Stone Dusting

“ANY dust insoluble in the fluids of the respiratory passages and in sufficiently finely divided form to float in the air and be breathed by underground workers will ultimately be harmful to health if the dust is in large quantities and is breathed by workers for considerable periods of time,” said D. Harrington, U. S. Bureau of Mines, in his paper at the fourth and final session of the Industrial Relations Committee, American Institute of Mining and Metallurgical Engineers, Feb. 20. “This applies to insoluble non-mineral as well as to mineral dusts or mixtures of them, and includes coal dust or mixtures of coal and other dusts.”

Dr. A. J. Lanza read Mr. Harrington's paper in his absence, and in commenting on it, stated that the latter had said many things that were unquestionably true. It has long been believed that coal miners are immune to tuberculosis, but more recent investigations would indicate that this may be far from true. Insurance statistics do not bear out the miner's immunity, and coal dust does not appear to immunize the lungs to the tubercular bacillus. If the ordinary tubercular risk, so far as an insurance company is concerned, may be regarded as being 100, that of the coal miners would be 475.

B. F. Tillson stated that fine dust seemed to be soluble in the lung fluids. He inquired concerning the relative danger of drilling upper holes and those drilled horizontally, and asked if the dangers from wet drilling are as great as those from dry drilling. Also, he wanted to know if limestone produced a dangerous dust. He called attention to the fact that every one breathed more or less dust and that it is probable that city dwellers take more fine particles of foreign matter into their lungs than do workers in metal mines.

In reply, Dr. Lanza said that in drilling upper holes the dust falls down almost directly upon the driller and gives the worst possible condition. In wet drilling heavy air pressures passing through hollow drill steel force dust back out of the hole in air bubbles. Naturally these burst and release the dust into the air.

IS DUST DRAWN TO DRILLER BY EXHAUST?

Some one then asked if the suction created by the exhaust of the drill might not draw the dust issuing from the mouth of a horizontal hole toward the driller. It was stated that some experiments tended to substantiate this idea. It was also said that ordinary limestone dust might be taken into the body in large quantities without bad effect, it being dissolved and thrown out practically as fast as it was absorbed. It was said also that sulphide dust appears to be no worse than any other dust. In general, the effect produced by any dust upon the human system is in proportion to the exposure to that dust, or, in other words, to the dosage.

The discussion then turned upon the physiological effect produced by stone dusting in the mine. Mr. Rice stated that in England and France, coal dusts were neutralized for explosions with limestone or shale dust, and in Great Britain rock dusting has been made compulsory by law. Experience so far would justify the belief that no ill physiological effects have resulted from this neutralization.

Ordinary wetting of coal dust has proved a failure in preventing dust explosions, but rock dusting appears to set up an efficient barrier to the propagation of the explosion flames. No physiological troubles have been experienced in Great Britain from stone dusting, although the English use a shale dust which contains as much as 30 per cent of silica. It is therefore believed that rock dusting is safe both from the explosive and the physiological standpoint.

ASTHMA DECREASING AMONG COAL MINERS

Mr. Taylor then stated that asthma appears to be on the decrease among miners. It is believed that modern coal-mine ventilation is sufficient to sweep out any dust which may be formed before it has time to act harmfully upon the miners' lungs.

Mr. Tillson said that mining men necessarily must compromise in seeking conditions theoretically correct and must submit to the requirements of practical mining. The ideal would be to allow no dust within a mine, yet stone dust is needed to prevent explosions. Furthermore, practical mining demands that blasting be done throughout the day, whereas the ideal would be to perform blasting only at night or when no men were in the mine. He asked what was the danger point so far as the quantity of dust allowable in mine air was concerned, and stated that this would be valuable knowledge from a practical standpoint.

In reply, Mr. Rice said that the Bureau of Mines has not yet reached any satisfactory conclusions on this point, but that investigations are progressing. Much experimental work already has been done, but the conclusions deducible from it have not yet reached even an approximately final stage.

Mr. Tillson suggested that in view of the importance of the dust hazard in mining a symposium upon it be held at the next annual meeting. It is quite probable that the Institute will take some action upon this point in the near future.

J. T. Ryan addressed the committee on industrial relations in European coal mines, illustrating his talk with a series of excellent lantern slides. He stated that European mine conditions differ greatly from those prevailing in America, but we may nevertheless learn much from Europe's problems in industrial relations and their solution.

European mines are constructed for operation over long periods, sometimes for as much as 400 years. All top works, as well as the miners' houses are built of durable materials and are designed to last for an equal length of time. The French pay more attention to welfare work than the British mine operators, and they have fewer strikes. Mr. Ryan's talk and slides show conclusively that continental mine operators pay far more attention to the human factors in mining and study more carefully than do those of Great Britain what might be termed the human failings and idiosyncracies of their workers.

W. R. Chedsey in the course of his remarks stated that the law of supply and demand cannot be superseded by state or national statutes. The slogan of a living wage for the worker is not all that might be desired. A better one would be a living wage and more for the workers with ample opportunity to earn it. The basis of payment for any person in an industry should be only that of value received, and the living wage should be earned and not gouged out of the public by union power or other means.

Theory and Practice in Air-Table Cleaning and Results Attained in Field Operation*

What Pressure Is Needed to Lift Particles and to Raise a Bed of Coal from the Table—
Screens and Dust Collectors Now Work Without Trouble—Ash
in Some Coal Reduced 64 per Cent

BY RAY W. ARMS†
Chicago, Ill.

DRY cleaning, or pneumatic separation, is not, strictly speaking, a recent discovery. Among the archives of the Patent Office may be found many patents dating back as far as 1850 which cover early attempts to separate materials of varying specific gravity or of different shape by means of air. Hundreds of patents covering this art have been issued, which may be roughly classified into four general groups, as follows:

1. Stationary devices with pulsating air currents. In these the separating surface is usually riffled and air is supplied by bellows or compressors. This group also includes air jigs, which have been used rather extensively.

2. Stationary devices with continuous air currents. These submitted the material to a continuous current of air, either horizontal or vertical. Chaff is blown from wheat by such a device.

3. Reciprocating or vibrating devices with pulsating air. A small group in which the pulsating air is supplied by bellows and some motion provided in the separating surface to move the stratified material to various discharge points.

4. Reciprocating or vibrating devices with continuous air supply. This is by far the most important group,

and all recent developments have been of this description.

All these groups of machinery involve the stratification of material by air and include none of the dry cleaning devices that use other principles, such as the coefficient of friction, magnetism, etc.

In all the groups of air separating devices already mentioned the same phenomena are found as exist in water concentrators; that is, free settling will be found in some and hindered settling in others, with a complex action on the reciprocating tables similar to the wet tables.

The experimental value of the settling ratios of particles in air has never been determined but, following the formulas given in Richards' "Ore Dressing," they can be calculated. The formula for the settling velocity of particles in any medium is as follows:

$$V = C \sqrt{(d - d_1) D}$$

in which V = velocity of the particle; d = density of the particle; d_1 = density of the medium; D = diameter of the particle and C = a constant depending on the shape of the particle and the units used. This constant has never been determined for coal or slate, but in my estimation that for slate will be about 0.85 of that for coal because the slate is usually in tabular form.

To determine the free-settling ratio, which is the relation between diameters of particles settling in a

*Article entitled "Dry Cleaning of Coal," read at the February meeting of the American Institute of Mining & Metallurgical Engineers, New York City, Feb. 18-21.

†Contracting Engineer, Roberts & Schaefer Co.

medium at the same rate, the two velocities are equated and the ratio of the diameters determined. Thus:

$$100\sqrt{D_1(1.3 - 0.00124)} = 85\sqrt{D_2(2.6 - 0.00124)}$$

$$\frac{D_1}{D_2} = \text{free settling ratio of coal and slate in air} =$$

1.4, where D_1 = the diameter of the coal particle and D_2 = that of the particle of the slate.

In wet concentration, it is a known fact that the hindered-settling ratio is much larger than the free-settling ratio, and it is reasonable to suppose that the same holds true with air separation. From experiments that have been made so far, it is reasonable to assume that the hindered-settling ratio is approximately 2.5. This ratio governs the sizing that must precede concentration and will vary in different coals.

The theoretical calculation of the quantity of air that will be required to suspend a bed of raw coal sufficient to cause stratification is indeterminate, owing to the fact that this suspension is accomplished partly by the static pressure and partly by the velocity of the air; but the two limits caused by these factors may be found, and the calculation is determined to that extent. The effects of these two factors may be observed best by considering the extreme cases: first, of a single particle of coal being lifted or suspended by a blast of air; second, of an air-tight bed of particles being lifted by air pressure.

In the first case the lifting power of a blast of air is roughly equal to its velocity pressure. For example, a velocity pressure of 0.1 lb. per sq.in. will have an equal buoyant effect over the surface of the particle. Any particle weighing less than 0.1 lb. per sq.in. of cross-section will be lifted by this velocity and, conversely, a particle of more than this weight will sink. It is assumed in this discussion that the particles are roughly cubical or spherical and that the area subjected to the action of the air is cross-sectional area.

For the particles of any other shape, the minimum cross-sectional area should be used, as the particle will assume a position in a blast of air that will bring its long axis parallel with the direction of the air current. It is manifest that the above theory will be somewhat complicated by the eddying air currents, which vary considerably with the shape of the particles. It is presumable that cubical particles would be easier to support than flat slabs or more or less "stream-lined" shapes. The formulas required to figure the lift on a particle are derived from the elementary physical formula $V^2 = 2gh$; in which V = velocity of air in feet per second; g = force of gravity, and h = head in feet. In this discussion, this formula means that a pressure in pounds per square inch equal to the weight of a column of air 1 sq.in. section and h ft. high will cause air to flow at the rate of V ft. per second. For example, 0.1 lb. per sq.in. pressure at 32 deg. F. and 30 in. of mercury is obtained by a certain height of a column of 1 sq.in. section:

$$\text{Weight of air} = 0.080975 \text{ lb. per cu.ft.}$$

$$\text{Column 1 in.} \times 1 \text{ in.} \times 1 \text{ ft.} = \frac{0.080975}{144} = 0.000562 \text{ lb.}$$

$$0.1 \text{ lb.} = \frac{0.1}{0.000562} = 177 \text{ ft.} = h$$

$$V = \sqrt{2 \times 32 \times 177} = 106 \text{ ft. per second} = 6,360 \text{ ft. per minute.}$$

The size of coal that will be sustained by this velocity can be calculated by determining the size of particle having a weight of 0.1 lb. per square inch of sectional area. Using the cube as the shape:

0.047 lb. = weight of 1 cu.in. coal at 1.3 sp.gr.

Let x = any dimension in inches,

then $0.047x^3$ = weight of the coal particle,

$$\frac{1}{x^2} \text{ number of particles covering 1 sq.in.}$$

$\frac{1}{x^2} \times 0.047x^3$ = weight of 1 sq.in. of particles, but the particles weigh 0.1 lb. per square inch. Therefore, $\frac{1}{x^2} \times 0.047x^3 = 0.1$ and $x = 2.1$ in. Thus the velocity pressure of 0.1 lb. per square inch representing a velocity of 6,360 ft. per minute will support a 2-in. cube of coal.

Conversely, the velocity required to support any size of particle may be calculated as follows: Assume a $\frac{1}{2}$ -in. cube of coal,

$$\text{Weight per square inch} = \frac{0.047}{2} = 0.023 \text{ lb.}$$

$$h = \frac{0.023}{0.000562} = 41 \text{ ft.}$$

$$V = \sqrt{2 \times 32 \times 41} = 51 \text{ ft. per second} = 3,060 \text{ ft. per minute.}$$

Thus air at a velocity of 3,060 ft. per minute will support a $\frac{1}{2}$ in. cube of coal.

The second factor entering into the stratification of coal by air is the static pressure under the bed. If this bed of coal were so closely packed as to be airtight, the total pressure acting upon it would be the maximum pressure the fan or blower could produce. If a centrifugal fan or blower is used, it is possible to maintain a pressure as high as 8 or 10 in. water gage and this entire pressure would be exerted to lift and loosen the bed of coal until a certain air velocity could be obtained. The lifting power of this static pressure is quite high and is found as follows:

$$1\text{-in. water gage} = 5.2 \text{ lb. per square foot}$$

This will balance a solid bed of coal 0.77 in. deep; 8-in. water gage will balance $8 \times 0.77 = 6.16$ in. of coal

A fan of the type generally used, therefore, will provide sufficient static pressure to open up any bed of coal that may be put upon it but usually will not provide sufficient air to support the particles by velocity pressure alone unless the particles are very small.

In the operation of a dry-cleaning table, the air actually used is much less than is required to completely support the particle, and the pressure of the air immediately below the coal bed is low as compared with the maximum pressure the fan will generate. The condition sought is a loosening of the bed so that the refuse will sink and the coal tend to float. To obtain this condition it is necessary to find the balance between the weight of the particles involved and the static and velocity pressures of the air.

As cold air is heavier than hot air, less of it will be required by volume to support the coal, but the velocity pressure will remain the same. More power is required to move equal volumes of cold air but the requirements of cleaning will remain practically constant, as less of the cold air is required. In rarefied atmospheres, fan speeds should be relatively higher.

This discussion of theory leaves much to be desired in the way of a definite basis on which to make calculations but it is hoped that it may suggest some starting points for investigation, which will bear fruit in the form of data and constants which will be useful in the future development of the art of dry cleaning.

A large plant using air cleaning tables is being built and tested at McComas, W. Va. This plant started

cleaning coal about the first of May, 1923, and has been operating more or less continuously since.* During this time the cleaning tables have operated with entire satisfaction. No structural defects have developed, and the tables have established themselves as efficient coal-cleaning devices. However, there have been unforeseen difficulties at McComas which have delayed the successful operation of this plant as a complete unit.

The collecting system proved to be inadequate for the large volumes of dust created in handling Pocahontas coal by methods of this kind. This problem was submitted to the B. F. Sturtevant Co., which installed a complete new system that is now handling the dust in a satisfactory manner. The failures of the original installation at McComas and at Raton, N. M., were due to the fact that the volumes of air handled through the dust-collector system were too small. The present system uses large volumes, large pipes, and large collectors, with a power consumption only slightly greater than the original system.

The screens originally installed at McComas were of the anti-gravity type with a head motion and details used for the first time on the McComas installation. This type of screen shows certain structural advantages, particularly in its adaptability to use on a level floor, but it had not been sufficiently developed mechanically to withstand the hard usage to which the screens were submitted, and breakage of parts frequently interrupted operation.

The vibrators which enlivened the screen surface also gave trouble and inefficient screening so interfered with the operation of the tables and caused the circulation of so much dust in the air, which should have gone to the undersize, that it was decided to replace the screens with Hum-Mer units, of which the operating characteristics are well known.

A 150-ton per hour dry-cleaning plant is now under construction at Wyco, W. Va. This is being built for the Wyoming Coal Co. This plant is designed and built by the Roberts & Schaefer Co., and uses the same types of pneumatic separators, dust collectors and screens as those mentioned as now being used in the McComas plant.

A dozen or more dry-cleaning tables are in course of development. Some are in the experimental stage, some are being transferred to coal cleaning from the field of ore concentration, and one at least is being included in the equipment of a plant under construction. None, however, has been placed on general sale except the American pneumatic separator.

This separator is capable of cleaning coal as large as 2 in. diameter and as fine as 100-mesh, by using the proper deck for the size treated. The coal is first sized so that the finest particles in the feed are about half the diameter of the largest. This limitation in the variation in size is found to give the best effect. The capacity of the table varies according to the size of the

coal; the table for coal of about 1 in. diameter having the highest capacity, namely, about 25 tons per hour. The power required to operate the table, including fan, head motion and feeder, also varies according to the size of the coal and the capacity and has its maximum at about 25 hp.

The cleaning tables at Raton, N. M., are of a smaller type than the so-called American pneumatic separator, being designed primarily for seeds, grains, and ores, but they are fully as effective, except that they have a lower capacity than the types installed at McComas and also at Wyco.

In all the tests made on this separator, the coal has been prepared for cleaning by a preliminary screening into several sizes. This has been the practice at the Raton and McComas plants, for thereby the best possible cleaning is obtained. Given the advantage of close sizing and middlings return, the pneumatic table will closely approach perfect cleaning on the sizes treated.

By perfect cleaning is meant the complete removal of all material heavier than a certain predetermined specific gravity, with the loss of none of the lighter

TABLE II—DRY CLEANING RESULTS AT RATON, N. M.*

particles into the refuse. This perfect cleaning may not produce a clean coal with as small an ash content as may be desired, but if not, it is the fault of the coal and not of the cleaning.

If this perfection of cleaning is not required, and it is desired merely to remove a portion of the heavy material, it can be done with the dry-cleaning tables without such close sizing. Also, those coals which have small proportions of bone coal and other constituents of intermediate specific gravity will require less attention to sizing than coals with much of this material.

For efficient dry cleaning, therefore, close sizing is essential, but a considerable reduction in ash can be accomplished without it.

For the most efficient screening into the various sizes, the feed should be reasonably dry. Coal that is dampened by moisture other than "inherent" moisture screens with difficulty and carries much of the fine clinging material into the oversize. This is no great detriment to table operation except that it cuts down table capacity by subjecting much material to treatment from which it receives no benefit.

Coals which contained as much as 12 per cent of water have been treated on these tables with good results. It may be said, therefore, that any coal that can be screened can be cleaned. Thus the matter of superficial moisture in the coal becomes purely a screening problem, and even should the coal be screened on

Hydraulic Stowage at Home and Abroad

In European Mines Rock Is Crushed and Flushed into Mine
—When Workings Are Filled Hydraulically as Much as Forty
Feet of Coal Has Been Removed Under a City Without Damage

OF PARTICULAR interest to coal-mining engineers whose properties lie in densely populated regions, or those where the value of the surface is great, was the session of the American Institute of Mining & Metallurgical Engineers devoted to ground movement and subsidence. This meeting which was held in the Engineering Societies Building was presided over by Mr. Moulton. As a preliminary to the meeting proper, he described the methods employed in tunnel driving through sand in building subways in Brooklyn.

This procedure more nearly resembles that of forepoling than any other method normally employed in mining. Cuts about 2 ft. in length are made at a time. A small hole about 2 ft. in depth is driven in the upper right- and left-hand corners of a face and short props inserted. A third hole is then driven in the center of the tunnel at the top and another prop or a forepole inserted. Next, a thin slice is taken between these openings and a plank placed under the roof supported by a prop and the timbers in rear. When the slice has been taken clear across the upper portion of the face, planks are inserted and held up by timbers while the balance of the cut is taken out.

PACK EXCAVATIONS WITH BROKEN ROCK

Following this, George S. Rice presented a paper on ground subsidence and surface support as practiced in European mines. In France, it is considered that subsidence of the surface after mining is inevitable and all excavations made underground are filled. This filling is usually done by hand, the rock being packed with extreme care. Hydraulic filling is, however, employed in certain regions. Both the mine refuse and rock from the surface are employed in building the packs.

In hydraulic filling, where no sand or gravel is available, stone is quarried on the surface and crushed to suitable sizes before being taken into the mine. Hand stowage is done in an extremely careful manner. The ultimate subsidence experienced with careful hand filling is kept down to about 50 per cent of the depth of coal removed.

An excellent example of hydraulic stowage is found in Saxony. Here, about 40 ft. of coal is being removed and more or less destructive subsidence of the surface was present on the outskirts of a somewhat populous city. As a result, the city authorities were loath to grant permission for removal of coal inside the corporation limits. Permission to remove the coal from under the city was finally obtained, however, provided the workings were filled hydraulically. This has been done and the surface subsidence is only 5 to 10 per cent of the thickness of the coal removed. Practically no destructive effects are visible on the surface.

Mr. Rice showed a number of excellent lantern slides illustrating surface subsidence and its effect. Among others was shown a picture of an engine house that had settled about 20 ft., without material damage to the hoist engine. The shaft which this engine served, however, was thrown out of alignment. Another picture showed a beautiful old stone church, probably dating back several hundred years. This also had been subject to a settlement of about 20 ft., without any perceptible damage being done. Some of the other views showed stone dwelling houses in which slight wall cracks had made their appearance but which easily could be repaired. In some of the other illustrations, whole streets of populous towns or small cities had settled, due to the coal being removed from underneath them, yet no cracks had developed in the street pave-

Slush Discharge

This shows the delivery end of the flushing pipe. The silt or other material employed is retained in the rooms or other places to be filled by means of "batteries" or bulkheads so built as to allow the water to drain through them while the flushing material is retained.

ment. In comparison to some of the mine cave-ins and other troubles common in this country, this would appear to be a truly remarkable accomplishment.

Although various kinds of pipe and various pipe materials have been employed for hydraulic stowage, present practice throughout continental Europe seems to have settled upon ordinary cast iron. This pipe is made with flanged connections and long sweep fittings. Such pipe possesses the advantage that when worn from the abrasion of the material which it carries, it may be turned to four separate positions so that the pipe may be practically completely worn through before it is necessary to discard it.

In some mines, large quantities of granular materials are used in stowage. For instance, in some places as much as 5,000 cu.ft. of sand is flushed down a single shaft daily. The pre-war cost of this stowage was about 25c. per ton of coal produced. In some instances, the flushing materials, such as sand and gravel, are dug by steam shovel on the surface and transported several miles before being flushed into the mine.

Another and somewhat peculiar type of stowage was found by Mr. Rice. In one place, all coal is being taken out from under a river of appreciable size and the void space thus made is being filled with a weak concrete. This is being done to shut all river water out of the mine and effectively prevent subsidence of the river bed.

ANTHRACITE REGION THINKS STOWAGE COSTLY

In the discussion of this paper in response to an inquiry from the chair, R. V. Morris stated that the conditions existing throughout the anthracite region were materially different from those described by Mr. Rice. Hydraulic stowage in mines, beyond question, had its origin in the anthracite region, the first work of this kind being performed in the early 70's. Nevertheless, this method of surface support has never been extensively used in anthracite mines. In fact, the material there used for stowage has been confined almost exclusively to mine waste and the grade of fine coal now known as "slush," or that which passes a $\frac{3}{4}$ -in. circular opening.

Enough material to successfully flush the anthracite mines is not available in that region and little hydraulic filling is now being done there for the purpose of coal recovery alone. The principal advantage of this method of mine stowage is the prevention of damage to property on the surface, and many of the upper beds are now being filled in this manner. While the northern anthracite region might contain sufficient surface sand and other drift for flushing material, the cost of utilizing it would be prohibitive under ordinary circumstances.

Mr. Rice then asked Mr. Norris if he did not think that cities in time would demand hydraulic filling and that material would also be flushed under the beds of rivers and large streams to prevent the strata from fracturing through to the surface and flooding the mines.

In reply, Mr. Norris stated that conditions prevailing throughout the anthracite region had undergone a great change during his own recollection. In the past forty years, during which time he had been actively connected with the mines, commercial mining had been carried on in beds from $5\frac{1}{2}$ ft. down to 2 ft. in thickness. In other words, forty years ago, a $5\frac{1}{2}$ -ft. bed was the thinnest that it was considered commercially possible

to mine. Today, a 2-ft. bed is thus treated. It is possible that in the future the price margins realizable for coal may be such as to permit hydraulic stowage of the coal measures, but Mr. Norris did not feel that that time had yet arrived or that it lay in the immediate future.

H. N. Eavenson then stated that a questionnaire bearing on this subject had been sent out to about one hundred coal-mine operators. Approximately two-thirds of these questionnaires had been returned, the majority of them lacking the information most desired. This was probably due to the fact that the management of the ordinary mine does not keep accurate records of the amount of surface subsidence that takes place over its workings. He believed, however, that by the end of the year, all available information would be in hand and ready for presentation at the next annual meeting.

H. Eustace Mitton stated that the paper and discussion had been of particular interest to him. Hydraulic stowage had been attempted in Great Britain only in extremely rare instances. Throughout that country, approximately 90 per cent of the coal was produced by longwall mining. This method of operation permits the withdrawal of coal from under surface structures with little or no damage to them, so long as the faces are kept advancing at a fairly uniform rate. A cessation of operation, however, over any appreciable period of time brings on trouble.

LONGWALL CHEAPER THAN ANY STOWAGE

During the great British coal strike a year or two ago, much damage was done to surface structures at points directly above or near the coal faces. Mr. Mitton stated that it was his opinion that the longwall system of mining would be cheaper than that employed in this country, if the places thus mined had to be stowed in order to prevent destructive subsidence and damage to the surface.

Charles Enzain stated that he had heard of a method of mining and back-filling that consisted of driving rooms, say 25 ft. wide and leaving pillars of approximately the same width or slightly wider between them. After a room had been driven, the bottom was shut up and the top shot down. Next, a narrow entry would

Flushing Pipe Entering Through Borehole

Refuse from picking tables and jigs is crushed at the breaker and flushed immediately into the pipe leading into the mine. This is a bell-and-spigot cast iron pipe the joints of which are made tight by wooden wedges.

be driven through the pillar left between rooms. This would be driven to the end of the pillar, when short crosscuts, either way, would be driven to the rock filling now occupying what had been the original room. These wing pillars would then be drawn back as rapidly as possible, the top being shot down and the bottom shot up meanwhile. If the top could be shot down to a sufficient height, so that the voids in the loose material would equal in volume the coal taken from the bed, it is probable that this system of back-filling would work successfully.

From the paper and the discussion it would appear that a certain quantity of surface subsidence is unavoidable if any large percentage of the coal is to be extracted from a bed. The real problem of the engineer conducting such operations is therefore, not to avoid subsidence, but to control it so as to nullify its destructive effect upon the surface or surface structures.

The Miner's Torch

Everybody's Business

LAST week I chanced into a friend's office (he is a coal-mine superintendent) and noticed the following proverb, neatly framed, hanging over his desk: "Let every man mind his own business and the cows will be well tended." When I entered the office I found my friend away for the day and his secretary, a rather attractive young woman, trying to amuse herself by executing pictures on her typewriter. The pictures were not word pictures but typed illustrations.

"Could you type a cow in that manner?" I asked, and was immediately sorry that I had been so brusque because she instantly looked up at the proverb and appeared to be greatly embarrassed.

Finally, but not without embarrassment to myself, I succeeded in convincing the young lady that I had had no intention of connecting the work she was doing with the precept on the wall; at least, not in the manner which she had assumed.

Then I explained that what I had desired to do was to make a few comments concerning the framed proverb, for the benefit of her boss, who happened to be one of my best friends, and it had occurred to me that a picture of a cow at the top of the sheet which I proposed to use would help to gain his attention quickly.

Of course, womanlike, she was curious to know what I proposed to write. Without further urging on my part, she put a blank sheet in her machine and began to hammer away at the keys; in a very few minutes she handed me a sheet with a creditable looking cow at the top. Seeing that I was pleased with her efforts, she offered to type underneath the comments that I proposed to make. This put the joke back on me because while watching the young lady manipulate the typewriter keys I had entirely forgotten what I had intended to say. Eventually, however, I managed to dictate thusly:

"Following most any cow path leading out of your village into the surrounding country, you will come face to face with a gang of moonshiners who are allowed to attend to their own business simply because you

and the other law-abiding citizens of your community feel that you ought to attend to your own business."

"These moonshiners have probably 'salted' away during the past two years about one-half of the total earnings of a good many of your employees, and today they might buy the controlling interest in your company if their ambitions ran in that direction. That they have been attending to their own business with a vengeance, no one can question. And what have they given your camp in return for all of this money? Poverty! sickness! and death! Sure, every one knows that! But if a man wants to risk his life for a drink or two, of course, that's his business.

"Just a word now about the last clause of the proverb: 'the cows will be well tended.' Some men would starve their families before starving their cows, but even so you can find plenty of instances of cows having been starved because the money that should have purchased feed has been used to purchase whiskey. And consider the cows that have been taken from their stalls and led out to be exchanged for whiskey. Undoubtedly, they are being 'well tended'; most moonshiners are country bred and their preference runs to milk rather than whiskey."

When I arrived home I found a telegram awaiting me. It read as follows: "Who tends the cows on your lot?" It carried two signatures, my friend's, the superintendent, and his secretary.

Car Body Built of Corrugated Sheets

FOR seven or eight years cars have been built in Great Britain at Bolton, Lancashire, with the body composed of corrugated sheets. Where a large area of a flat sheet would be distorted by a blow, a corrugated sheet would be affected only locally. The plate is bent around the car corners in a cold state by patented machinery without the sheets being thinned or stretched in any way and without the corrugations being lost at the angle. In fact, what is a sag on one side of the angle is a high spot on the other side. In consequence the angle stands out well and is quite stiff, not needing any stiffeners inside or outside the body.

Each car body is composed of five sheets, four corner bolts and four binding pins, no rivets whatever being used. Plates can be bundled and shipped insuring a low freight rate. The labor cost of assembling and repairing the plates is low, only a hammer and a wrench being needed for that work. In fact it is claimed that a body can be put together in five minutes single-handed, whereas a wooden or riveted steel body requires two men, one of whom must be skilled, several rivets, a furnace and some hours' work. The sheets are made interchangeable.

The manufacturers claim that the cars thus constructed have a long life and that the maintenance costs are low, that they are dust proof—a condition we are only just beginning to appreciate—that they save in weight of body and so reduce haulage costs and handling effort, that they last at least 100 per cent longer than riveted steel bodies and in general will not need repair for four or five years.

Of course, a car with corrugated sides does not dump as readily as one with smoother surfaces but where rotary dumps are used as in England and in parts of this country, an easy discharge of the coal, slate, sand-rock or clay in the car should be obtained.

Broadcasted Program Received In Depths of Mine

Whole Evening Program Received 400 Ft. Underground
—Possible Developments May Exert Great
Influence on Industry

BY EDGAR GEALY

IN THE early stages of radio experimentation, it was learned that when an oscillatory electrical discharge occurred, part of the stored energy setting up the disturbance was spent at each oscillation. Later it was found that these oscillations caused electro-magnetic strains or stresses in the all-pervading ether. In 1863 Maxwell formulated the theory that these disturbances traveled at the speed of light—186,000 miles per second. Some time later Hertz set up these disturbances, detected them and proved that they possessed many of the properties of light and radiant heat.

We have since learned that radio waves have many qualities much different from these and are not so closely limited in their range. When radio-telegraphy was developed, many of us were astonished to find that our sets could pick up messages on an indoor aerial, and we therefore concluded that the waves were capable of penetrating the walls of buildings. Not long ago we were somewhat surprised to learn that radio messages were picked up by a receiving set located in one of the Hudson River tunnels. This experiment was made under a great depth of water, but not being satisfied with this pioneering work, the men interested in the test decided to try the experiment in a mine. On Feb. 14 the test was successfully made and radio took one more forward step.

Many engineering men interested in radio will attach much importance to the success of this test. Radio engineers have long since believed that radio waves travel through buildings and even mountains, but their vertical penetration into the very bowels of the earth was something not altogether believed possible. The conditions in mines differ greatly from those in buildings or under rivers; they are often hundreds of feet deep and often covered with beds of coal—carbon—which might reasonably be expected to act as an absorbent or shield to all kinds of waves. Nevertheless, the experiment was entirely successful and has consequently opened up great possibilities.

Who knows how great a factor radio may become

Testing the Penetration of Radio Waves

Down where the dusty diamonds are mined, these men found radio waves which carried perfectly both human voice and music.

Music in Mine Air 400 Feet Underground

Here in the mine mules' pantry the party set up their instruments and heard station WQAN—"Willie Quick And Nellie."

in the mining industry; some of us are already cognizant of its possibilities in the homes of miners and mining officials. It is no wild stretch of the imagination to see how easily it may supplant the house organs and bulletins of mining companies and at the same time engender a more intimate contact between the mining officials and the men. It is easy to see a coal-company president sitting at home in the evening talking to his men, telling them how to do their work more safely and efficiently or even refuting the arguments of some Bolshevik who has been sowing seeds of discord at the mines during the day. In times of storms, floods, explosions and other mine accidents, how much more satisfactory and reliable will radio be than the wired telephone. Will those of us who like music with our noonday meal be outdone by our brother, the miner?

Whatever possibilities the future may hold, the men who conducted the test at the Pine Brook mine in Scranton, Pa., all agree that they had a real thrill as they sat in the mule barn in the Baltimore No. 2 vein and heard James Walsh sing "A Kiss in the Dark."

Just a few minutes before the strains of the music echoed through the dark chambers of the mine, Ralph D. Bunnell, vice-president and general manager of the Moon Radio Corp. of Astoria, Long Island, New York, had entered the mine with a standard receiving set and stretched a 25-ft. aerial over some timbers and ledges of coal. After setting up the instrument in several different locations in the Baltimore No. 2 vein, the equipment was removed to the China vein and here, at a level 400 ft. below the surface and about a half mile from the mine shaft, the program was listened to until the operator signed off for the evening.

An interesting feature of the event was the fact that during one of the underground tests the receiving set was located quite close to the power circuits of the mine, but regardless of this, the sounds were received without distortion or disturbance.

We now know that radio waves will penetrate into the mines, and perhaps the day is not far distant when, by means of radio, we may be able to illuminate the mining face of gaseous mines, fire shots more safely or operate drills and cutters.

Everett Drennen

President of the West Virginia Coal & Coke Co.

AFTER much patient experimentation Everett Drennen put into operation the V-system of coal mining described in our issue of Feb. 7, a method the publication of which has caused a veritable sensation among coal-mining men.

Mr. Drennen for years has been a quiet force in coal affairs. He was chairman of the Fair Price Committee of the Northern West Virginia Coal Operators' Association in which capacity he assisted in driving to cover the speculators who had boosted the price of coal to unprecedented heights. After a persistent campaign the price was cut from around \$14 to \$6. The work of the committee was approved by the federal authorities, the results showing that when Mr. Drennen starts out to accomplish something he succeeds.

Mr. Drennen was born in Minneapolis, Minn., about 38 years ago. After graduation from the University of Michigan he obtained employment in the department of maintenance of way and construction of the Pennsylvania R.R., remaining with the company two years, and then entered Cornell University, where he took up civil engineering and was graduated in two years.

His first employment after leaving Cornell was as engineer of road construction of Belmont County, Ohio, where he remained until he joined the forces of the

Consolidation Coal Co., becoming associated with its power and mechanical department. During the first five years of his connection with that company Mr. Drennen must have devoted nearly all of his time to work, as he also was general manager of the Fairmont Mining Machinery Co. and construction engineer of the Monongahela Valley Traction Co. which also has its headquarters at Fairmont, W. Va.

In 1912 Mr. Drennen was transferred to Jenkins, Ky., as manager of the Elkhorn Division of the Consolidation Coal Co. operations, remaining there two years, when he became connected with the Stonega Coke & Coal Co. as vice president and general manager. He left that company in 1917 to become vice president and general manager of the West Virginia Coal & Coke Co. and three years later was made president of the company, which position he still occupies.

The West Virginia Coal & Coke Co. was organized by the First National Bank of New York City to take over the coal holdings and operations of the Coal & Coke Ry. and the Davis Collieries Co. and allied interests of the Henry G. Davis estate and the Stephen B. Elkins estate. The company operates twelve collieries located in West Virginia having an annual output of about 1,500,000 tons.

News Of the Industry

Official Attitude on Trade Statistics Menaces Coal Industry

Data Essential to Intelligent Conduct of the Trade—Deadlock of Departments of Justice and Commerce May Require Intervention of President—Friendly Lawsuit May Be Way Out

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

The uncertain status of trade statistics brought about by the activities of the Department of Justice has affected the coal industry seriously. It has all but disrupted the statistical activities of the National Coal Association. Since statistics are so essential to the intelligent conduct of the coal trade, it is hoped that this industry will be able to bring about a clarification of the situation. Allen H. Willett, director of the Bureau of Coal Economics of the National Coal Association, has called attention to the fact that the Department of Commerce and the Department of Justice are in deadlock and that the President might be induced to force the issue to a conclusion. A suggestion from another quarter is that a test case could be brought in a clear-cut statistical case without the consent of the Department of Justice. It is understood that the Department of Justice has declined to initiate such a proceeding.

Under Sec. 7 of the Sherman Anti-Trust Act, any person injured by any violation of the act is given expressed permission to sue in any Circuit Court in the district where the defendant resides. For example, any consumer of Pocahontas coal who might be convinced that, as a result of the statistical activities of the Pocahontas Operators Association he is being injured, could seek an injunction. A case could be brought equally as well against any other of the local coal associations. While it would be a friendly suit, it is thought essential to the case that the consumer bringing the action should view the matter in much the way as is done by the Department of Justice.

Those who are keeping closely abreast with the trade-statistics situation are convinced that no industry is more dependent on current facts and figures than is coal. It will be recalled that Secretary Hoover pointed out during the last strike that, had figures been available on the rate of consumption, prices would not have mounted as they did. Such figures would have squeezed much of the speculation out of the situation. The need is accentuated by the far-flung character of the business. Conditions in one

field affect, directly or indirectly, the situation in the others.

There never was a time in the history of the coal business of this country when figures were so necessary. The industry is entering upon a three-year armistice. A period of intense competition is ahead. The business situation is uncertain. Drastic curtailment of immigration is having its effect on the labor situation. If there ever was a time when careful and systematic planning was necessary, it is now.

The coal industry has the advantage of a better statistical foundation than have most industries. At this critical time, however, current returns on coal are being so curtailed as to impair their value materially. Many concerns that happen to be in a position to operate to advantage if some of their competitors have no figures to guide them are taking advantage of the Attorney General's activities to decline to make returns.

It happens also that there is a press-

Department of Mines Plan Gets More Indorsements

Indorsement of the Department of Mines bill continue to reach Senator Oddie. John Hays Hammond has gone on record favoring the plan in an unqualified way. The Nevada Senator also is in receipt of an indorsement of the bill from J. E. Spurr, which reads in part as follows:

"I am very strongly in favor of a Department of Mines and consider it absolutely necessary for the welfare of the mining industries and for the proper prolongation of the general business prosperity of the country. I do not think it should be regarded as a sop to the mining industries but should be considered as a help to the other industries that depend upon the proper conduct of mining, one of the greatest and most important of the basic industries of the country. You may be sure of my enthusiastic co-operation."

ing necessity just at this time to call the country's attention to some serious phases of the existing situation. It has been said rather glibly that the three years of peace which stretch ahead will be a good thing for the industry, in that it will eliminate a lot of high-cost mines. Reference to the statistical records of the U. S. Geological Survey will emphasize the fact that this squeezing-out process is going to be a serious one. In addition to all the wagon mines and the country banks, there are 5,000 companies engaged in the production of coal falling in the class with an output of less than 100,000 tons. All of the mines of these companies, which include the higher-cost mines, could be eliminated and still the country would have a capacity in excess of its probable needs during the next three years.

It is certain that these properties can not be relegated to a state of stand-by without trouble. If nothing else, their elimination would give rise to such dissatisfaction on the part of a large body of miners that a strike could not be avoided, many think. The situation is a serious one and one that calls for full facts, yet just at the time when the industry and the country need coal statistics most, the statistical foundation is threatened.

Fail to Agree in Kanawha; Wage Parley Broken Off

Cincinnati, Ohio, March 3.—After two days of negotiations on a wage scale between operators of the Kanawha district whose properties lie north of the Kanawha River and in what is known as the K. & M. territory and representatives of District 17 of the United Mine Workers, deliberations were broken off on Friday afternoon without an agreement having been reached. No statement was offered and it is believed from what little has been said that a parting of the ways has been reached.

No future date was set for resuming the conferences and those operators who attended the meeting say that there seems little likelihood of their continuing after April 1 except on an open-shop basis. The point at issue was the same as in the Tennessee-Kentucky arbitration case recently argued here. The operators believed that they should be allowed a scale which would allow them to compete with non-union fields adjoining. In the Kanawha field operators on the south of the river have been operating open shop for some time past with a wage scale of approximately \$4.68 per day as against \$7.50 to the north of the river.

Illinois Begins Three-Year Acid Test

Mines Are Shutting Down Fast—May Eventually Drop to Number Operating in 1914—Stripping Operations Increasing Rapidly

Shutdowns of many Illinois mines last Saturday night marked the real beginning, in that state, of the great three-year acid test of the coal industry. Ever since the signing at Jacksonville, Fla., Feb. 18 of the three-years continuance of the 1919 wage scale for the Central Competitive Field, Illinois operators have been trying to guess just where the inevitable lightning is going to strike within the state and how much damage it is going to do. The first shutdowns, numbering about a dozen mines, make up the opening touch of the storm. The general opinion is that there will be many flashes before April 1 and that the state has a hard row to hoe during the coming summer. However, nobody expects any collapse of the state's coal industry, but rather a purifying of it by fire.

There are 363 shipping mines in the state, not to mention the 800 locals. Of the shipping operations, less than 300 were producing at the end of 1923, but the number increased a little during January, when several mines got the best run they had had since the winter before. The mines which opened in order to get a slice of January business were sorely afflicted during February, however, and most of them are now down. It is estimated by one of the best-informed Illinois operators that by April 1 the number of properties ready to operate will have been reduced to 254, which was the 1914 total.

Salvation in Cost Cutting

A number of companies whose existence cannot be justified in the face of the conditions of the next three years will silently quit business on or before April 1. But also the big companies with strings of mines are preparing to close up all but the most advantageously situated operations within their ownership. This process, in fact, has been going on for months. Thus every sound company in the state is beginning by trimming down all the mines it can, thus obtaining the best possible working time for the others. The Old Ben Coal Corporation, for instance, is now running four out of twelve mines. Scrupulous care is exercised to reduce the cost of coal to the absolute rock bottom. Therein will lie the salvation of many a company, according to the prevailing sentiment.

Stripping in Illinois also is getting a great deal of close attention. "If I can't stay in business operating a shaft mine, then I'm going to try stripping," said a well-known mine owner, as he went over a sheaf of records on his desk comprising engineers' reports on several sections of possible stripping land in Jackson, Williamson and Fulton counties. Outside the Danville field, more than half the output of which is strip coal, there has never been much shallow mining in the state except a handful of shovel operations in Williamson County. During the autumn

of 1923, however, two great stripping plants and several small ones were opened in Jackson County and the Peoria field.

The Black Servant Coal Co., owned by the Hartshorn interests, of Danville, is operating at Elkville, and the United Electric Coal Co. began an important operation near Cuba. The next big strip put will be opened at once by the Gayle Coal Co.—the Crerar Clinch interests—south of Duquoin. These are expected to be followed into the field by several other companies, who hope to go into stripping on a big scale, get into production quickly, and produce coal for a little over \$1 a ton—if luck breaks their way.

But what effect is the three-year contract going to have on Illinois? The opinion of many operators boiled down produces little except the obvious. The number of mines will be reduced about one-third, but it will take at least eighteen months to accomplish that because of the fact that only a few companies are under pressure of short-term financial obligations and, history repeating itself, many a property will be handed around from owner to owner three or four times before the collapse. The state will see an intense effort of engineering and management to cut the cost of producing coal. Two or three tremendous new mines will turn out a great volume at the low costs which usually prevail in new operations whose haulage is short and ventilation charges small. Margins on coal will be trimmed down to extreme thinness to hold most of the markets the state serves.

And Illinois will go on about the business of producing and selling 60,000,000 or so tons a year with fewer miners than for any 60,000,000 tons it ever produced before. During 1923 nearly 90,000 miners got out the state's approximate 75,000,000 tons, but from now on there will be 50,000 or 60,000 jobs for men who can efficiently serve those Illinois mines whose output the country really needs.

Pays \$800 for Lost Miner

An insurance company has been required to pay the face value of a policy on the life of a miner in southern Illinois even though nobody could prove him dead. Seven years ago George Biondi went below in the Zeigler No. 1 mine, at Zeigler, Ill. At his working place eventually were found his dinner bucket and denim jumper, but he never came out of the mine and has never been found. After prolonged litigation the beneficiaries of Biondi won their case in the Circuit Court at Benton, Ill., last week and the insurance company was ordered to pay them \$800.

Alberta Coal Output Grows

More than 2,000,000 tons of coal produced in the Province of Alberta were sold at Canadian points outside the province last year. This statement is made in the annual report of the Alberta Mines Department recently presented to the legislature. The total output for the year was 6,866,923 tons. Of this 1,382,788 was consumed in Alberta; 1,937,753 tons was disposed of in other provinces and 83,557 tons went to the United States. While there was an increase in Alberta coal exports to the East it is shown that United States coal came into Canada from the Rocky Mountains eastward to Fort William to the extent of 1,151,629 tons in excess of the 1922 importations.

What are termed the domestic coal fields of Alberta produced 3,161,741 tons last year. Much of this came from the vicinity of the City of Edmonton, as is shown by the following details: Tofield, 104,886 tons; Clover Bar, 395,371; Edmonton, 130,112; Strathcona, 5,361; Namao, 13,264; and Cardiff, 72,139.

The production of the bituminous fields was 3,241,614 tons, of which the Crows Nest Pass Mines contributed 1,865,000 tons; the Brazeau Field, 493,378; Jasper Park, 248,659; and Mountain Park, 634,474 tons. The sub-bituminous fields produced 463,461 tons, the greater part of which came from the Yellowhead fields with 377,574 tons.

Loading Docks of the Cassidy Collieries

These collieries, located on Vancouver Island, are subsidiary of the Granby Consolidated Mining, Smelting & Power Co.

I. C. C. Takes Recess in Rate Case Till April 22

Southern operators and the railroads will have until April 22 to prepare their case in the Pittsburgh-Ohio rate controversy, the Interstate Commerce Commission having taken a recess until that date after conducting hearings from Feb. 13 to 21.

The case involves coal-freight rates from the so-called inner crescent territory to Lake Erie ports. It originated from a petition filed by the Pittsburgh Coal Producers Association alleging that rates from western Pennsylvania and eastern Ohio points to the lake ports were unjustly high and that rates from other points of competitive shipments were out of proportion in that they gave operators in these other territories a preferred position in lake coal business. The Northern West Virginia Coal Operators Association filed a similar petition in behalf of its members, directed against the Baltimore & Ohio and other railroads. A number of intervening petitions were filed in opposition.

The case was heard before H. C. Hall, chairman of the commission, assisted by Examiner Gerry.

Testimony in behalf of the petitioners was to the effect that differentials of 25c. per ton from the Pittsburgh district, and 28c. from Ohio and northern West Virginia, with 48c. from Kentucky-Tennessee mines, are not sufficient to properly care for the added mileage; therefore the rates from the petitioners' territories should be reduced to widen this differential. Many tables of statistics were introduced to establish that coal shipment to the lakes from distant points, at inadequate freight rates, caused the use of several thousands of cars annually during the lake season in excess of actual needs, because of longer hauls. The petitioners are deprived of the natural advantages of their geographical location because of the alleged preference in rates granted more distant points, it was testified.

The position of the Southern operators is that the case is a "gigantic effort on the part of Pittsburgh and eastern Ohio coal interests to eliminate the competition of Southern coals, thereby monopolizing the Lake and Northwestern trade." James D. Francis, chairman of the joint committee representing the Southern operators, commented on the case as follows:

"Unionized coal fields in the Middle West for several decades are alleged and are believed to have attempted to create a monopoly for their coals by conspiracies with the United Mine Workers, but, having failed, they now attack the existence of Southern producing fields by asking the Interstate Commerce Commission to establish prohibitory freight rates on Southern coals to Lake ports for transshipment to the Northwest.

"Southern operators contend vigorously that existing freight rates already are too high and should be reduced. Coal consumers of the Northwest should have the choice of coals from all coal fields now serving the Northwest. The

Seward Button

Formerly head of the State Department of Mines of Pennsylvania, Mr. Button has just been appointed vice-president and general manager of the Temple Coal Co., Scranton, Pennsylvania.

public should not be denied the only real substitute for anthracite coal nor be compelled to pay the exorbitant freight increases requested in connection with the attempt of Pittsburgh to create a monopoly."

Hoover Hails Renewal Of Old Contract

Agreement by the subcommittees of bituminous coal operators of the Central Competitive Field and of the United Mine Workers to submit for ratification a three-year extension of the present wage agreement was characterized by Secretary of Commerce Hoover at a press conference Feb. 26 as "the most constructive step in the industry in many years."

The effect of the three-year agreement, in the opinion of Secretary Hoover, will be to stabilize the soft-coal industry as to operations and also to stabilize prices.

Instead of a difference of as much as a dollar in the price of soft coal, the Secretary ventured the opinion that the long-term wage contract will result in a spread of only about 15c. in prices at the mines, due to competition. The price of bituminous coal f.o.b. mines probably will settle around from \$2.20 to \$2.40 per ton, Mr. Hoover predicted. The Secretary was speaking only of the effects of the agreement upon unionized mines. He did not touch upon the subject of the possible closing of high-cost mines.

By doing away with periodical strikes and threats of strikes, the agreement also will have a beneficial effect upon the railroads, Secretary Hoover said, by giving the carriers an opportunity to adjust their car supply.

Says Industrial Court Has Not Had Fair Test

As the result of a year's study the National Industrial Conference Board states that the Kansas Industrial Relations Court has not had a fair test of its ability to establish regularity and continuous operation in the face of economic conditions. The Conference Board's findings are set forth in a statement just issued. Released on the eve of the expected decision of the U. S. Supreme Court in the Howat case, the statement points out that many factors associated with the court in the public mind cannot be considered as evidence for or against the court.

"The Kansas Court of Industrial Relations," says the report, "has been a novel experiment, suggestive as a guide for future effort to meet a complex and difficult problem. It demonstrated the ability of such an institution to settle minor differences between employers and workers on the basis of fact and common sense. It furthermore provided a machinery by which larger group conflicts in industry might be systematically adjusted in accord with principles of industrial justice gradually to be developed out of experience. It did not develop its full potentialities of adjustment because three major conditions necessary to the success of such an institution under present circumstances were not fulfilled in it. These conditions are:

"(1) Acceptance by employers and labor unions in essential industries of the dominance of the public welfare and of the necessity for regulation of private action in the public interest. Such an institution as the Kansas court cannot effectively operate unless the public interest in and reasonable regulation of essential industries is sanctioned by public opinion.

"(2) Development of principles of law and rules of practice which will lead to the recognition and utilization by such an institution of the structure and processes of group organization in industry. The conflicts with which it must deal are conflicts of group interest, not disputes between individuals. The work of such an institution as the Kansas court must, therefore, be based upon and built up out of the machinery and processes of voluntary private collective bargaining, developed through effective and representative group organizations.

"(3) Complete removal of such an institution from the influence of partisan politics. Such an institution cannot successfully function as a commission dependent upon political appointment."

A NEWS ITEM appearing in *Coal Age* Feb. 7 bore the headline "Pittsburgh Coal Co. Takes Over Reiss Interests." To make the announcement perfectly clear to our readers perhaps it should be stated that the sale by the Reiss interests to the Pittsburgh Coal Co. consisted only of its mining property. No change in the control of the Reiss dock interest has taken place.

Shutdown Coming in Southwest

Operators Will Demand Wage Cut and Scale Conference Will Be So Delayed No Agreement Seems Possible by April 1—Operation Under Present Contract Pending Settlement Not Likely

A general shut down in the Kansas, Missouri and Oklahoma region is expected April 1 because the operators of the district are setting out to effect a reduction in miners' wages lest they all go broke before autumn. A wage-scale conference for the district is to be held, but probably not until March 25, because the last of the miners' delegates cannot be chosen until then, it developed last week after Charles F. Spencer, president of the Southwest Interstate Coal Operators' Association, and Commissioner W. L. A. Johnson had met Presidents William Bogartz, of the Kansas miners; Arch Helm, of Missouri, and Andrew McGary, of Oklahoma.

It is considered doubtful if, in the five days intervening between the ten-

tatively selected date of March 25 and April 1, when the present contract will expire, an agreement on wages will be reached. Operators declare they will demand such changes in the existing contract as will give substantial relief in the cost of production. They point to the number of mines of the district that were not opened this year, and say only a lessening of production cost can bring about full-time operation.

It is not likely that the two groups will get together in the few days allowed them before the termination of the existing contract. Neither is it considered likely that the mines will be permitted to operate under the present contract pending negotiations. Consequently the Southwest is expecting work to cease April 1.

Miners to Vote March 12 On New Agreement

Union coal miners in the Central Competitive Field will vote Wednesday, March 12, on the action of their International scale committee in regard to the new wage contract provided at the joint conference of miners and operators at Jacksonville, Fla., Feb. 19. Ballots for the referendum have been printed and will be distributed to approximately 5,000 local unions in Indiana, Ohio, Illinois and western Pennsylvania. Officers of the miners' organization believe that the three-year contract will be ratified by the miners by an overwhelming vote.

Annual N. C. A. Convention in Cincinnati May 14-16

Cincinnati has been chosen as the place at which this year's annual meeting of the National Coal Association will be held, May 14, 15 and 16 having been fixed as the dates for the meeting. Some of the committees will be called into session May 13. Arrangements have been made whereby the machinery exhibition of the American Mining Congress will be held in conjunction with this meeting.

The entertainment features of the program will include an evening barbecue on the nearby Kentucky farm where the American Bar Association was entertained recently in similar fashion. There will be a boat ride on the Ohio River during which a vaudeville program will be presented.

Census Data Indispensable to National Betterment

In a statement intended to justify expenditures for census purposes the British Government points out that the information as to the number and composition of populations is not asked "to gratify curiosity or merely to add to the sum total of human knowledge." Continuing the statement says:

"The cost of census taking is far too great to be incurred solely to provide interesting facts. The real necessity for the census is that it provides the only possible method of ascertaining from time to time the true condition, social and economic, of the people. This knowledge is indispensable, not only to enable the people to govern themselves and to carry on their national work but also as a starting point and foundation for all efforts and plans for the betterment of social and national conditions."

Probe Coal Thefts from Federal Reserves

Alleged usurpation and infringement upon government coal reserves in northern Alabama is to be probed, the U. S. Government having begun an investigation at Jasper, Ala., March 1, through the Southern Division of the General Land Office at Jackson, Miss., according to James W. Neal, in charge of the land office at Jackson.

Mr. Neal, who will have supervision of the investigation, stated that the government would investigate charges that millions of dollars worth of coal had been mined and sold from government property by private mine owners during the last few years.

High Finance in Coal

The hopelessness of the strong, legitimate coal man against the general condition of things in the trade is shown in this advertisement by the Western Fuel Co., Salt Lake City, Utah, headed "Somebody Fell Out of Bed": "Because one soft-coal dealer got peeved at another soft coal dealer he cut the price of coal 50c. per ton. Then the second dealer got peeved at the first and cut the price \$1. How can they do it? It can't be done and make any money. The coal dealers, therefore, are in very much the same fix as the lady who bought 'hot dogs' at 5c. each and sold them six for a quarter. When one of her competitors asked her how she could do it, she replied: 'Look at the volume of business I'm getting.' If you want to break the coalmen, buy all the coal you can at these ridiculous prices, and please remember that KING COAL—the best coal mined in Utah—is being sold at these same ridiculous prices, or any other price that will be made."

Rail Coal Consumption Lower During November

Class 1 railroads of the United States consumed 9,080,000 net tons of coal during November, 1923, as charged to account 394, compared with 9,411,000 tons in the preceding month and 9,755,000 tons in November, 1922, according to a report by the Bureau of Statistics of the Interstate Commerce Commission covering 176 steam roads. During the first eleven months of 1923 these roads consumed 100,799,000 tons as compared with 85,915,000 tons in the corresponding period of 1922. The delivered cost per net ton of coal consumed in road service in November last was \$3.27 as against \$3.30 in October and \$3.87 in November, 1922.

Consumption of fuel oil by the roads during November totaled 194,377,000 gallons compared with 198,760,000 gallons in the preceding month and 155,248,000 gallons in November, 1922. During the eleven months ended with November the roads consumed 1,795,283,000 gallons compared with 1,409,545,000 gallons in the corresponding period of 1922.

Entrance to Wilson Tunnel, Coalmont Collieries

The Coalmont Collieries, Ltd., is a British Columbia operation. The body of the mine car is lifted from the frame and carried up the tramway.

Coal Mine Accidents Took 234 Lives in January

Accidents at coal mines throughout the United States killed 234 employees during January, 1924, according to a report by the Bureau of Mines. Included in the fatalities are 68 victims of two explosions during the month at Johnson City, Ill., which caused 32 deaths, and at Shanktown, Pa., which caused 36 deaths. The fatality rate for the month was 3.94 per million tons, based on a production of 59,435,000 tons of coal. In January, 1923, the fatality rate was 3.52, based on 206 deaths and an output of 58,458,000 tons.

Bituminous-coal mines in all states reported 202 fatal accidents, the production being 51,470,000 tons, and the fatality rate being 3.92, as compared with 3.28 for January last year. For the anthracite mines in Pennsylvania, the reports covered 32 fatalities, which, on the month's output of 7,965,000 tons, indicated a fatality rate of 4.02 per million tons, as against 4.89 for January, 1923.

As compared with January, 1923, the reports for January of the present year indicated lower fatality rates per million tons for all of the main causes of accidents except explosions. For falls of roof and coal, the fatality rate per million tons declined from 1.85 in January, 1923, to 1.68 in January, 1924; for haulage accidents the rate declined from 0.62 to 0.42; for explosives, from 0.19 to 0.12; for electricity, from 0.12 to 0.07. The rate for explosions increased from 0.21 to 1.31 per million tons.

Coal Saves Fruit

Frost is one of the banes of the Northwestern fruit grower's life. When the word comes from the weather bureau that a touch of zippy temperature is due Tuesday night, the orchardists put in a busy Tuesday afternoon firing up the smudge pots under the trees. All sorts of fuels have been used with oil prominent among them. Just now a campaign is on in Washington State to induce fruit growers to use Washington coal briquets for the purpose. Thus the market for Northwestern coal is increased and the rest of the country gets more fancy apples—at 15c. each.

Portland Cement Production Lower in January

Production of portland cement during January, according to a report by the U. S. Geological Survey, based partly on estimates, totaled 8,788,000 barrels, compared with nearly 10,000,000 barrels in the preceding month and 7,990,000 in January, 1923. Shipments for the month were 5,210,000 barrels compared with more than 6,000,000 barrels in December and 5,628,000 in January, 1923. Stocks at the end of January amounted to 14,153,000 barrels, compared with 10,575,000 at the close of the preceding month and 11,477,000 barrels at the end of January, 1923.

No Move to Prevent Issuance Of Trade Information

Apparently the Department of Justice has no intention of attempting to call to account any trade association whose only activity is the distribution of unidentified statistical information. It has been suggested that a judicial determination of a case involving such statistics only would be extremely valuable in clearing up existing uncertainty as to the legality of such activities. The Department of Justice, however, never has taken steps against an association engaged in what always has been considered thoroughly proper statistical activities. For that reason there has been no judicial decision covering the legality of such activities. The only way a judicial clarification of the situation can be obtained is through some process initiated by the Attorney General. This he seems disinclined to do, even with the idea of bringing a test case.

E. N. Zern, Invalid, Rescued When Home Burns

E. N. Zern, editor of the *Coal Catalog*, was rescued with difficulty when a \$20,000 fire destroyed his home, at Crafton, Pa., last week. Mr. Zern, who is 65 years old and an invalid, having been confined to his bed for three years, was carried to safety only after four attempts to rescue him had been unsuccessful. Frozen hydrants near the Zern home greatly hampered the firemen in fighting the flames.

Coal-Mine Fatalities During January, 1924, by Causes and States

Practical Pointers For Electrical And Mechanical Men

Composition and Corrosive Effect of Mine Water

The U. S. Bureau of Mines, in co-operation with the Carnegie Institute of Technology and officials of the coal mining industry, has been studying the problem of corrosion of metals in the mines and many interesting results have been obtained.

In its broadest sense corrosion has been defined as that process which will cause a metal to revert to a state of more stable chemical equilibrium. This is accomplished by the interaction of the metal with a corroding medium, which may be a gas, a liquid, or a combination of both. The products of such a reaction are salts, hydroxides, or oxides of the metal.

Corrosion is evidenced by the formation of decomposition products such as coatings or precipitates, by a gradual wearing away of the surface, by the formation of pits, or by any or all of these in combination.

figures showing the range in composition for acid water from bituminous coal-mines.

Many factors influence the corrosive action of mine water, principal among them are the following:

- (1) Chemical composition of the metal or alloy.
- (2) Physical condition of the metal or alloy.
- (3) Chemical composition and concentration of the mine water.
- (4) Velocity of flow.
- (5) Temperature of the medium.
- (6) Time period of exposure.
- (7) Solution pressure of the metal or alloy which depends on 1, 2 and 3.
- (8) Electrical conditions of immersion.
- (9) Effect of light.

It is hoped that further study will bring about results that will help materially in the proper selection and care of metals used in mining machinery and equipment. Records of corrosion on rails, pumps, pipes and boilers will be thoroughly covered to ascertain the best means of reducing the present high depreciation.

iron involves many movements of great and small distances during the working day. The two tanks holding the gases, which form the mixture for the production of the high-temperature flame, are heavy and unwieldy, and for that reason a conveyance of some kind must be provided to give portability to the outfit. In many mine shops a two-wheel truck is used for this purpose, but this contrivance cannot be moved any great distance over the rough ground upon which the mine plant is very often built.

LEWIS MINE HAS TANK TRUCK

The Hudson Coal Co., at its Lewis mine, Wolf Summit, W. Va., rigged up a tank truck of lightly fabricated flanged wheels and seamless tubing, the latter being so cut and joined by welding to form a rack for the gas tanks. To two vertical post tubes is attached one stationary iron band which is curved to fit halfway around each tank and another band similarly curved that is hinged to one post and pinned to the other post. These bands form a clamp that may be closed to hold the tanks securely, or opened to permit replacement. The bottoms of the tanks fit in shallow recesses in the floor of the truck, which also is made up of tubes.

A pushbar is attached to the two post tubes furnishing a convenient means for moving the truck by hand wherever mine track is laid.

Mine Truck for Oxyacetylene Welding Outfit

Wide and varied use of oxyacetylene blowpipes at various mines for the duties of cutting and welding steel and

Truck for Making Welding Outfit Portable

This light truck can be easily moved around the mine yard or in the mines to any place where the track has been laid; thus the welding equipment is taken to the job and made more serviceable.

ARIATION IN THE COMPOSITION OF TYPICAL MINE WATER FROM COAL MINES IN PARTS PER MILLION

Constituent	Low Value	High Value

SO ₄	790	12,115
Suspended matter (on unfiltered water) dried at 150 deg. C.	6	91
Acidity due to free sulphuric acid	Trace	3,662
Acidity due to free sulphuric acid plus sulphates of iron and aluminum	2,180	17,200

The composition of mine waters varies according to the locality of the mine. The water from any particular mine will vary according to the season of the year, the age of the mine and other factors. Water which has been allowed to flow through old workings usually is more acid than water from a new opening.

The acidity of mine water is due to the presence of free sulphuric acid. The mine water also will usually contain considerable amounts of sulphates of iron and aluminum, and smaller amounts of sulphates of calcium, magnesium, sodium and potassium. Silica and chlorides usually are present. In some mines the chloride content of the mine water is sufficiently high to be a serious factor. In the table are given

Dynamos and Failure to Excite

When a direct-current dynamo is brought up to speed it should in a few moments commence to build up voltage or, in other words, excite. Failure to do so may be attributable to a variety of causes, the principal ones being broken shunt field circuit, weak residual magnetism, insufficient speed, the brushes not making contact with the commutator and wrong direction of rotation.

The shunt winding of the dynamo being wound with comparatively fine wire must be carefully handled, especially the ends that are brought out for connection to the armature. A break in the shunt winding obviously will rob the machine of its magnetic field and it would be unable to build up any voltage except that due to residual magnetism, which would be of very small value. It sometimes happens that the residual magnetism of a new machine is weak, and great difficulty is experienced in getting the generator to build up voltage. This is not likely to happen with a machine after being in service a short time, but it does occasionally happen with machines when first received from the manufacturer. The difficulty, however, is easily overcome by disconnecting the shunt field from the brushes and connecting it to a number of dry cells, or accumulators, supplying a pressure of from 10 to 12 volts. The machine should then be run up to speed, but the connections of the cells to the shunt field may have to be reversed so as to send the current through in the proper direction.

When the voltage has been built up sufficiently to indicate that the current is passing around the field in the same direction as that which would be supplied from the armature itself when running under ordinary conditions, the dynamo may be stopped, and with the cells still connected to the field the magnet iron may be given a few gentle blows with a hammer, as this assists the set of the magnetic poles. After the cells have been disconnected and the proper connections made to the armature there should be no further trouble in getting the voltage to build up as soon as full speed is reached.

Some machines retain more residual magnetism in their poles than others and will commence to build up voltage before the armature reaches its maximum speed, while on the other hand should the residual magnetism be weak it may be necessary to run the generator for a few moments slightly above full speed, in order to give the field a start in building up. These cases are seldom encountered, but their possibility in actual practice should be borne in mind.

Failure to excite owing to brushes not making contact with the commutator is not common, though it may easily occur on a machine having an eccentric commutator. This causes the brushes to slide to and fro in the brush boxes and when the brush gear is allowed to get dirty and considerable quantities of carbon find their way into the brush boxes, the brushes become stiff and do not readily slide. Thus there is the possibility of their sticking

as the machine slows down, the high part of the commutator lifting the brushes, which then stick up, so that only the high part of the commutator comes in contact with them. To avoid this trouble, brush-holders should always be kept free from carbon dust and other matter, so that the brushes can slide freely in their holders, and follow up any wear which takes place.

Wrong direction of rotation will prevent the building up of a field of a direct-current dynamo because immediately the armature begins to generate current due to residual magnetism. The direction of the E. M. F. generated is such as to send the current round the field coils in the opposite direction to that necessary to increase the residual magnetism, and consequently the one neutralizes the other, and the magnetic field cannot build up.

If the direction of rotation cannot be changed, the shunt-field connections to the armature should be reversed.

ENGINEER.

Proposed Specifications For Trolley Wire

Recent tentative specifications drawn up by the American Society of Testing Materials to cover round and grooved trolley wire may be abstracted as follows:

The material shall be electrolytic or low-resistance lake copper conforming in quality and purity to the requirements of either the specifications for electrolytic copper or lake copper of the society.

Round Wire.—(a) Shall be so drawn that its tensile strength and elongation shall not be less than the following:

VALUES FOR TENSILE STRENGTH AND ELONGATION

Diameter, In.	Area, Circular Mils	Tensile Strength, Lb. per Sq. In.	Elongation in 10 in., Per Cent
0.548.....	300,000	47,000	4.50
0.460.....	211,600	49,000	3.75
0.410.....	168,100	51,000	3.25
0.365.....	133,225	52,800	2.80
0.325.....	105,625	54,500	2.40

The elongation shall be determined as the permanent increase in length due to the breaking of the wire in tension measured between bench marks placed upon the wire originally 10 in. apart. The fracture shall be between the bench marks and not closer than 1 in. to either bench mark.

(b) Tests upon a section of wire containing a braze shall show at least 95 per cent of the tensile strength of the unbrazed wire.

(c) Electric resistivity shall be determined upon fair samples by resistance measurements at a temperature of 20 deg. C. (68 deg. F.). The wire shall not exceed in resistivity 900.77 lb. per mile-ohm.

Grooved Wire.—(a) The physical tests shall be made in the same manner as those upon the round wire. The tensile strength of grooved wire shall be at least 95 per cent of that required for round wire of the same cross-sectional area; the elongation shall be the same as that required for round wire of the same cross-sectional area. The twist test shall be omitted.

(b) Tests upon a section of wire containing a braze shall show at least 95

per cent of the tensile strength of the unbrazed wire. Elongation tests shall not be made on test sections including brazes.

(c) The requirements for resistivity shall be the same as those for round wire of the same cross-sectional area.

For the purpose of calculating weights, cross-sections, etc., the specific gravity of the copper shall be taken as 8.89 at 20 deg. C. (68 deg. F.).

Round Wire.—(a) The size shall be expressed as the diameter of the wire in decimal fractions of an inch, using not more than three places of decimals, expressed in mils.

(b) Wire is expected to be accurate in diameter. Variations of 1 per cent over or under the nominal diameter shall be permitted.

Grooved Wire.—Standard sections of grooved trolley wire shall be those known as the "American Standard Grooved Trolley Wire Sections."

(a) Size shall be expressed as the area of cross-section in circular mils, the standard sizes being as follows:

300,000 cir. mils weighing 4,795 lb. per mile
211,600 cir. mils weighing 3,382 lb. per mile
168,100 cir. mils weighing 2,687 lb. per mile
133,200 cir. mils weighing 2,129 lb. per mile

(b) Grooved trolley wire may vary 4 per cent over and under in weight per unit length from the standard as determined from the nominal cross-section.

Finish.—(a) The wire shall be of uniform size, shape and quality throughout, and shall be free from all scale, flaws, splits and scratches not consistent with the best commercial practice.

(b) Necessary brazes in trolley wire shall be made in accordance with the best commercial practice.

Packing.—All wire shall be shipped on substantial reels, suitable for the weight of the wire handled, and shall be well protected from injury. The length or weight of wire to be wound upon reels shall be agreed upon in placing individual orders.

Inspection and Rejection.—(a) All tests governing the acceptance or rejection of the wire, unless otherwise specified, shall be made at the place of manufacture with apparatus furnished by the manufacturer and in the presence of the purchaser or his representative, who shall be furnished a copy of the tests.

(b) For the purpose of determining and developing defects which may be prejudicial to the life of trolley wire, owing to its peculiar service as compared to that of copper wire for other purposes, the wire shall be subjected to the following twisting test: Three twist tests shall be made upon samples 10 in. in length between the holders of the machine. The twisting machine shall be so constructed that there is a linear motion of the tail stock with respect to the head. The twist shall be applied not faster than 10 turns per minute. All three samples shall be twisted to destruction and shall not reveal under test any seams, pits, slivers or surface imperfections not consistent with the best commercial practice. At the time of fracture the wire shall be twisting with reasonable uniformity. Wire shall not be considered satisfactory which does not withstand at least nine turns before breaking.

Problems In Underground Management

What Should We Do to Cope with the Ever-Present Dangers of Coal Dust?

**Spraying Necessary to Supplement Humidification—Coal Handling
Especially Dumping of Coal in Mine Dangerous—Alabama
Has Many Mining Machines Equipped with Sprays**

BY JOHN WALLS, SR.
Bayview, Ensley, Ala.

HUMIDIFYING mine air by the use of steam has been strongly advocated as a means of rendering coal dust harmless and reducing the danger of a dust explosion in mines. I remember an article that appeared some time ago in *Coal Age*, setting forth in considerable detail a method of humidifying the intake current of a mine that was operated on the exhaust system of ventilation.

Recent disasters in coal mines and our knowledge of the explosive conditions arising from the mining, loading, hauling and sometimes the dumping of coal in mines surely should convince us that these conditions cannot be overcome simply by maintaining a saturated mine atmosphere. In other words, humidification is not all that is necessary to prevent the occurrence of dust explosions in dry and dusty mines.

It is not my desire to discourage the use of steam in the intake current entering a mine but rather to emphasize that this should not be done to the exclusion of other means for the same purpose. In my opinion, the use of steam will not compare economically with a good spraying system installed in the mine and is not as effective in reducing the dust danger.

Who is there that has not noticed the dangerous condition of the atmosphere in a place being mined by an electric chain machine? I have often been unable to recognize the machine runner at a distance of 20 ft., so dense would be the dust floating in the air. There is no question but that such a condition is extremely dangerous owing to the possible short-circuiting of the current at some unprotected point.

The distribution of dust on the haulage road by coal falling from the cars and by the dust being blown from the coal in transportation, particularly in the use of cars that are not dustproof, presents another grave danger. Then, worst of all, arrangements sometimes are made to dump the mine cars into skips at the foot of the slope or a revolving dump is installed and the coal dumped into a hopper to be hoisted from the mine. In many cases an electric motor is in operation at the foot of the slope or shaft, where the danger is in-

creased owing to the high velocity of the air current.

For these reasons a good sprinkling system carried throughout the mine workings is by far the safest plan of reducing the danger from dust. But when all is said it is safer to concentrate our minds and energies on means of preventing dust than on rendering it harmless and non-explosive when it has been formed. The recent recurrence of explosions warns us that this is the reason of greatest danger and calls for the exercise of every possible precaution.

Mention was made some time ago in *Coal Age* of the application of water to the electric chain cutting machine. The device has been successfully used in

several of our Alabama mines. The plan involves the installation of a 1½-in. pipe line on the entries and the carrying of a ½-in. pipe into each working place.

The cutting machine is equipped with a half-inch copper pipe laid in a groove or slot cut in the right-hand rail of the cutter bar and extended so that the end of the pipe is close to the cutting bits. A 50-ft. length of hose is used to connect the machine with the pipe line at the face. The machine is thus enabled to travel easily the length of a 35-ft. breast.

By this arrangement the water is projected into the cut made by the machine and the dust thoroughly wet down by the spray. The water is under a pressure of about 100 lb. per square inch. The use of this device has wholly eliminated all traces of coal dust produced in the cutting of the coal. Moreover, by spraying the loose coal and the face after blasting, the coal can be loaded, hauled and dumped without a perceptible sign of dust floating in the air. Wherever coal-cutting machines are in use this plan of applying the water to the cutting machine when in operation should be adopted with a view to obtaining a maximum degree of safety and avoiding the dust danger.

Wide World Photos

Caging Mine Cars at the Wilhelmina Coal Mine, Holland

It will be noted that the cage is at least a two-decker. Two cars in an upper deck can be seen in the upper part of the illustration, apparently loaded from the other side of the stage. It will be seen that the cars are what we would term "baldies," the coal not being heaped above the sides of the car, doubtless to prevent coal waste and the sprinkling of the roadways with broken coal and coal dust. Coal is hoisted at a speed of 36 ft. per second, or 24½ miles per hour.

Production And the Market

Caution Dominates Bituminous-Coal Market; Consumers Lack Incentive to Purchase

Caution prevails throughout the coal trade. Producers, dealers and consumers seem to be playing a waiting game—the objective not being clearly evident. The government report of reserve stocks having revealed a goodly total sufficient for more than immediate needs in most quarters and the Jacksonville agreement having given an assurance of peace in the Central Competitive Field for three years, the incentive to buy has been removed for most consumers.

Even the trimming of prices here and there has failed to quicken the markets, most consumers being content to rely on their stockpiles where possible, making only necessary purchases from time to time, hopeful perhaps that further cuts will be forthcoming. A spell of mild weather also has played its part in the prevailing condition of inactivity.

Coal Age Index dropped 1 point to 183, as of March 3, the corresponding average price being 2.21. This compares with \$2.23 on Feb. 25.

Mild Weather a Handicap in Midwest

In the Middle West the market became more disheartened with the appearance of moderate temperatures, the melting rays of sunshine bringing to light cancellations and hold-up orders from all directions. Price trimming on coarse coals ensued among some operators, a number of others shutting down their mines and drawing their fires. Conditions are unusually bad in the Duquoin and Jackson County field. A slight improvement is observable in the Mt. Olive situation. Mines in the Standard district are working two and three days a week. Demand for Kentucky is rather dull, many of the larger markets being well supplied for immediate needs. It is considered not unlikely

that there will be a strike over renewal of an expiring wage contract in western Kentucky in April. Kanawha operators and miners' representatives held a two-day session at Cincinnati last week, but failed to reach an agreement. Negotiations were broken off and no date was set for another meeting.

Utilities Buying in Northwest

Most of the coal moving off the Head-of-the-Lakes docks is going to utilities and railroads. Some companies in the Northwest are putting the larger sizes of anthracite through breakers in order to obtain nut and stove sizes to fill contracts. Stocks of free bituminous on the Duluth-Superior docks are estimated at between 1,600,000 and 1,700,000 tons. In the Southwest the surplus of lump is still growing, though screenings move readily. Few "no bills" on industrial coal have come to light. Conditions in the Ohio markets are spotty.

Pittsburgh operators, fully tied up by the Jacksonville agreement, evince considerable interest in the wage situation in non-union Somerset County, where further cuts are said to be contemplated. Demand throughout New England continues weak. Similar conditions obtain in Atlantic seaboard markets.

Output of bituminous coal during the week ended Feb. 23 was 10,337,000 net tons, according to the Geological Survey, a decline of 802,000 tons compared with the previous week. Anthracite production also declined, the output being 1,655,000 net tons, a falling off of 245,000 tons when compared with the preceding week.

The anthracite market has become strictly a weather proposition, consumers showing little disposition to fill

Estimates of Production

(a) Revised from last report. (b) Subject to revision.

their bins with spring just around the corner. Dealers show a disposition to be cautious also, most of them trying to so regulate stocks as not to be caught with large tonnages on hand when April rolls around.

Midwest Screenings Strengthen

All over the Middle West the coal market continued to sag during the past week. Domestic trade softened under the warming rays of the sun and cancellations and hold-up orders from buyers came in from all points of the compass. The result is that every group of operators began to trim here and there on coarse-coal prices although new circulars were not issued until the beginning of this week, and these touched little but Indiana coals, which go off from 25 to 50c. on the big sizes. A new southern Illinois list will be out by March 15.

Meantime mines shut down and draw their fires, thus further reducing the production of the Midwest states. Simultaneously screenings strengthen in price as the supply dwindles. The painful thing about this is that a good many screenings contracts are being filled with coal bought by the operator on the open market at 25 or 50c. above the contract price. Central Illinois is particularly afflicted.

Free steam coal is strong at \$1.75 with a good many \$1.20 contracts running to April 1. Southern Illinois screenings are pushing hard against a \$2 price and will ascend soon.

Eastern coals coming into the Midwest do poorly. Good eastern Kentucky lump does well to bring \$3.25 and is on its way down. Pocahontas lump and egg move in small quantities at \$3.50@3.75 and mine-run is sinking from \$2.50 to \$2.25.

Field Activity Dwindles

In the Duquoin and Jackson County field conditions are unusually bad. Operators there are trying to get the prices that the independents are asking in the Carterville field, which range from \$3 up for lump and egg and from \$2.50 up for nut. The association Franklin County operators are still asking their circular but cut when necessary.

The Mt. Olive situation shows a little improvement. There has been a steady demand for the cheaper grades of coal and this domestic tonnage is moving freely and enough steam business is available for the nut and screenings.

In the Standard district cold weather has kept an even flow of tonnage, but some mines have unbilled coal of all sizes on track. Weather does not make any price change now. Everything is sold at about cost of production or less and mines are working two and three days a week.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924	1923
March 3	183	279
Feb. 25	184	279
Feb. 18	186	279
March 5	183	279
Weighted average price	\$2.21	\$2.23
	\$2.25	\$3.38

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

St. Louis Is Still Alive

While cold weather continued dealers found an active market for small quantities of the middle and cheaper priced coals. The local trade is fairly well satisfied as to the domestic movement on cheaper coals. There is a good supply of anthracite, smokeless and coke, with just a small demand. Wagonload steam continues good. The demand locally for screenings is fair, but the outside demand is better, especially from Chicago and the Northwest. Adjacent territory on steam is slow. Country domestic shows a little activity, but in minimum amounts.

Kentucky Does Little

With many of the larger markets well supplied with Kentucky coal for immediate use, and no special need of stocking far in advance, the coal jobbers and brokers are finding things dull. Mines are offering coal more freely, as short bookings have been fairly well filled, and many companies haven't much business. Car supply is good, labor in good supply, and loadings are really a question of sales and nothing else. Prices at the mines are being well maintained, as they are so low as to leave little chance for reduction.

Things are slow in western Kentucky, demand for prepared sizes having slumped somewhat, resulting in smaller production of screenings and slightly stiffer prices on pea and slack. Many mines are expected to shut down soon. There probably will be a strike in one section of the western Kentucky field in April over renewal of an expiring wage scale agreement. Indications are that there will be more mines welcoming contract business this year than usual, especially mine-run tonnage. Prices show practically no change, starting at around \$1@\$.1.10 for the cheapest of screenings and going to \$3 for best block coal.

Northwest Trade Lulls

Throughout the Northwest, markets quieted down during the past week. Coal continues to move off the docks, but the softness of the weather will surely cut down buying, especially since water power will begin coming back into its own and steam plants will let down. Most of the coal moving off the Head-of-the-Lakes docks goes to public utilities, which must keep their bins full, and to railroads. The only change in prices during the past week was a slight stiffening of Pocahontas screenings.

The situation for anthracite stove and nut has become serious. Some of the companies are putting egg through breakers to make it smaller, so as to fill out contracts. It is still possible to find stove in isolated cases, but others than "steady customers" must content themselves with egg, pea and buckwheat. It is hoped that the breaking will help. The weather is very mild at present and many have let their fires go out. Surveys made by two of the dock companies show that sales of anthracite this year were only one-third those of 1922.

Coal men estimate that stocks on Duluth-Superior docks March 1 will total between 1,600,000 tons and 1,700,000 tons of free bituminous. The larger figure is set as the possible maximum if many of those who have made contracts endeavor to backslide.

In Milwaukee heavy users of coal are holding off in expectation of a shading of prices in the near future. It is said that reductions in the cheaper bituminous grades are being secretly made now in an effort to reduce stocks before spring sets in. Stocks on the docks are heavy and a large tonnage undoubtedly will be carried over into next season. Several cargoes remain afloat. These will have to be unloaded soon in order to permit vessels to make necessary repairs.

Western Business Dull

Mines through the Southwest are working only three or four days a week, while the surplus of lump continues to grow. Screenings are moving readily. Few "no bills" of industrial coal are reported. As the demand falls off, price shading increases, but there has been no change in circular prices. Kansas coal still is quoted at \$5 for lump; \$4.25 for nut; \$3.50 for mine-run and \$2.25 for screenings.

Operators and dealers in Utah describe business as rotten. Production for the state is down to less than two days a week. Nothing seems to be moving but slack, and that is getting very scarce. Prices are unchanged.

The Colorado coal market has again slowed down slightly as compared with the past few weeks. The mines worked only on a three day average last week. This is attributed to the warm weather throughout the regions where Colorado coal is marketed. This being the case, it is expected that business will be stimulated considerably by the seasonable weather now prevailing for the past few days throughout Kansas and Nebraska. Prices are unchanged except on Colorado nut, which has been lowered to \$4.

Business Spotty in Ohio

Business in the Ohio markets is spotty. The course of the market at Cincinnati during the past week showed a downward tendency, production having risen to the point where the market finds trouble in digesting and absorbing what the brokers and wholesalers have to offer. Slack was the main point of attack during the week. The makers of prepared coal again misjudged the amount that could be taken by the retailers, who came in howling for coal during the cold snaps to the north. With everybody and his brother, seemingly, in southeastern Kentucky and southern West Virginia turning fuel over the screens, the residue had to be moved at concessions. There was no change in the price of specialized coals except that one or two of the

top-notch grades were being offered at \$3.75 for the block. The Cleveland market is in the doldrums. Operators and jobbers say that inquiries are lacking, but despite the lack of demand, spot prices have held pretty firm and no reductions are noted. As a matter of fact, "distress" coal has practically disappeared from the market. Steam buyers generally are now resting on reserves accumulated in anticipation of possible labor difficulties, and these will no doubt have to be depleted before they enter the market to any significant extent. Public utilities are doing likewise.

Domestic buying at Columbus has fallen off because of higher temperatures and the steam trade is dull. Buying is for immediate needs mostly, as there now is no disposition to stock up for the future, since the wage scale has been settled. Reserves in the hands of steam users are still large, although they have not been increased recently. Buying is slow along certain lines, especially public utilities, where reserves are extra heavy. Railroad demand is quiet, as roads are not doing much contracting at present. A good demand for smokeless is apparent on all sides.

The Southern Ohio Coal Exchange reported for the week ending Feb. 16 from 440 mines an output of 195,920 tons out of a full-time capacity of 570,459 tons, leaving a loss of 374,539 tons. In the eastern Ohio field during the same week 12,218 cars were ordered, of which 12,170 were placed and 9,228 cars were loaded.

Pittsburgh reports that demand for coal in the spot market, which had been extremely light for about three weeks, has shown a further decrease since the Jacksonville conference. The light demand has not affected prices to any appreciable extent, operators holding onto former prices with considerable tenacity. The only competition seems to be in the non-union districts, where further wage reductions are said to be contemplated. In the past few months about half of Somerset County has been at lower wages than the other half, and the latter is now beginning to come down. Additional wage reductions are not unlikely in the Connells-ville region. Thus far the coal produced for coking has been at the full scale, reductions being by producers of coal for steam purposes.

Central Pennsylvania operators probably will hold a conference with the miners March 15, at the conclusion of the miners' convention which will begin at Altoona March 11. The Jacksonville agreement is expected to have a strong influence on the conference.

Trade at Buffalo is as dull as ever. Operators and jobbers alike are grumbling.

New England in Grip of Doldrums

In New England the market continues dull with no relieving feature. Buying is only for scattering amounts and is pretty much restricted to Southern coals. Practically all the larger consumers are eating into their reserves for current consumption, there being no inducement now to add to present stocks. In no direction is there any demand for spot coal, and the trade as a whole looks forward to a long druggy season.

In spite of light demand the Southern agencies are able to hold prices with reasonable firmness at about \$4.75 per gross ton f.o.b. vessel. There is enough Western business at around \$2 per net ton at the mines to hold the tidewater basis, but it is possible that a reduction in wages in certain districts will at any time lead to naming lower figures. Coastwise there is a fair amount of tonnage moving on contract, but offshore cargoes are few and far between.

At this end prices are rather demoralized. Not only is Pocahontas and New River an easy purchase at \$6 per

gross ton cars Boston or Providence but retail prices are on an equally low plane. The open price is \$7.50 per net ton delivered by truck, but it is freely said that \$6.50 is the actual figure on close business.

All-rail there is next to no new business. Most of the central Pennsylvania operators realize that there is little opening for their product in New England under present conditions and that the Hampton Roads shippers are to have the call.

Seaboard Markets Show Little Change

Activity still is of low visibility in the Atlantic seaboard markets. New York dealers are glum. Coal shipped to New York without order is kept moving, but the tonnage is not large and prices are low. Contract coals are taken in good volume, but consumers with large reserves are beginning to hedge. Contracting is reported in some quarters as progressing favorably while other shippers say consumers are holding off, preferring to take chances in the open market. Philadelphia consumers keep buying to about the same degree as during the past two or three weeks. No heavy orders are recorded, but business seems to come along steadily, with just the least sign of increase in buying. The April contract business is growing more active, producers showing a desire to get tonnage under agreement.

The Baltimore market continues to mark time, as there is little real interest in the situation other than purchases for fill in necessities. A record for the number of export coal ships cleared during any single day of this year, as well as the largest amount loaded on foreign consignment, was made on Feb. 21, when cargoes amounting to 16,829 tons were loaded into four steamers at local piers. Baltimore dealers report selling a fair amount in small lots to householders who have not enough fuel to carry through the months of March and April, but the trend of the market is toward decreasing volume. Dealers here are waiting word as to conditions after April 1, and there will be little ordering in the meantime.

Anthracite Output Easily Absorbed

Weather conditions are affecting the anthracite situation at New York to such an extent that independent producers are having difficulty in placing their tonnage. There is a fair movement, however, and production is being easily absorbed. Egg and pea coals are the hardest to move while the demand for stove and chestnut is such that the best grades of independent product are quoted at from 50c. to 75c. above company circular. Some of the companies continue to store pea coal. The steam coals are in fair shape. Buckwheat No. 1 is the easiest, with rice a close second. Demand for barley and birdseye is strong, some shippers claiming a scarcity of both sizes.

It has been a good week at Philadelphia from the retailers' standpoint, as moderate winter weather has prevailed. The sizes in greatest demand continue to be stove and nut, with a leaning toward stove.

Foreign Market And Export News

British Coal Production Gains Steadily; Shipments Irregular

Production by the collieries of Great Britain during the week ended Feb. 16, according to official reports, totaled 5,821,000 tons, a special cable to *Coal Age* states. This was an increase of 17,000 tons compared with the output for the previous week.

The Welsh steam-coal trade shows marked firmness, all the collieries being well booked for the first half of the month. In some cases, in fact, they are oversold. The possibility of a strike of coal miners in the spring, following in the wake of the recent railway and dock strikes, is tending to make prices hold firmly and no doubt plays a part in the brisk inquiry for early supplies. Prompt shipments are hampered by the scarcity of ready tonnage, but conditions are rapidly improving. Concessions are being allowed to buyers who are able to take immediate deliveries.

The demand from the Continent is steady and there is fair business with South America. The foreign demand for Welsh anthracite is slow, though domestic inquiry has improved.

The Newcastle market is still very active. The business in steams, smalls and gas coals is especially good. Inquiries are circulating from the United States and South America for April shipment. Gothenburg gas works has taken 10,000 tons of gas coals for shipment before the end of March, and various other European gas works have contracted for smaller amounts for around 30s. per ton c.i.f.

Outlook Bright at Hampton Roads

Business at Hampton Roads shows little change in volume, although several foreign contracts have been reported and overseas trade appears on the increase. Coastwise business has been deterred somewhat by bad weather, as has bunkers.

Prices remain about the same. Con-

tracts with dealers in South America and Italy were on the basis of about \$4.85 at the piers, and an increase in movement was regarded as temporary. The general outlook in the trade, however, is brighter, and the tone of the market firmer.

French Market Dull in Domestic Coal; Industrials Better

The French market shows little animation as far as house coals are concerned, the demand having slackened with the approach of spring. Trade in industrial coals is better, however. Output of French collieries is scarcely sufficient to fill requirements and some complaints are still being made of irregularity in supply of cars at the mines for every-day shipments.

The new tariff accepted agreed to by the French companies on Feb. 1 will be in full force by April, when contracts are renewed; some of the coal now coming to the Paris area takes the new reduction of 3 fr. per ton. As a result of the cut, French coals, formerly the most expensive in the world, will actually be the cheapest.

The Belgian Cabinet also has asked its collieries to reduce their prices 10 to 15 fr. per ton. The proposal has been accepted, but the companies are trying to effect a reduction of 8 per cent in miners' wages. Settlement of the matter is expected soon, and the outcome is awaited with considerable interest.

With the settlement of the railway and dock workers' strikes shipments from Great Britain have increased markedly.

The S. C. O. F. supplies from the Ruhr for the whole month of January were 283,076 tons of coke, a daily average of 9,130 tons. This represents the highest average reached since the Ruhr occupation.

Lignite Rate Hearings Held

The hearings in the Dakotas on the proposed revision of the freight rates on lignite were held last week and the week before, in Aberdeen, S. D., and Bismarck, N. D. The Northern Pacific Ry. started the matter with a proposed revision of lignite rates to bring them into the same general distance schedule as those from the docks. The change is opposed by the lignite operators, the railroad commissions of Minnesota and both Dakotas and various other bodies. The railroads contend that the low rates, considerably lower than the rates on dock coal, were made during the war, to encourage the use of the nearest fuel and to save transportation. They seek to bring them into harmony with the other rates.

Larger Share of Through Rate Denied Sewell Valley R.R.

The effort on the part of the Sewell Valley R.R. to obtain a larger proportion of the through rate on coal moving over its line and that of the Chesapeake & Ohio has failed, as a result of a decision handed down by the Interstate Commerce Commission.

Eastern Rate Probe Ends

The Interstate Commerce Commission brought to a close on Feb. 29 its investigation of rates on anthracite and bituminous coal from points in Pennsylvania and other Eastern coal-producing states to New York and New England destinations. Briefs in the case must be filed not later than April 1, it was announced. Oral arguments probably will be made before the commission before the case is finally submitted for decision.

Attacks Coal Rates from Illinois To Indiana

The Old Ben Coal Corporation has filed complaint with the Interstate Commerce Commission, attacking rates of the C. C. C. & St. L. Ry., the C. & E. I. R.R. and the Illinois Central R.R. on bituminous coal from West Frankfort, West Frankfort Mine No. 18, Christopher, Christopher Mine No. 20, Johnson City and Buckner, all in Illinois and in the "Southern Illinois" rate group, to all points in Indiana, on the C. C. C. & St. L. on and north of the line of that road extending from and including Sanford, via Terra Haute, Indianapolis, Greensburg and Shirley, Ind., to and including Crete, Ind.

The complaint alleges that rates from said points of origin to all points in Indiana on the line of said railway extending from and including Martinsville to and including Fairland, Ind., and extending from and including Columbus to and including Greensburg, Ind., are unjust, unreasonable and unduly discriminatory.

The complaint is based on the fact

that the rates complained of exceed the rates on bituminous coal contemporaneously maintained to said destinations on shipments from coal mines in the so-called Group No. 1 (Harrisburg, Ill.) district as defined in C. C. C. & St. L. Tariff L. C. 139 F, I. C. C. No. 7836.

Rate Cuts on Coal Held Up By Illinois Judge

An order of the Illinois Commerce Commission reducing rates on coal from Springfield, Ill., to Bloomington, Ill., and from Lincoln, Ill., to Bloomington, Ill., has been held up in a ruling by Judge E. S. Smith in the Circuit Court at Springfield, Ill. The Chicago & Aiton contested the rate reduction and obtained the stay pending an appeal from the order of the commission. The lower rates were obtained through the action of the Bloomington Association of Commerce. Under the new rate fixed by the commission the tariff on coal from Springfield to Bloomington is cut from \$1.42 to 80c. a ton.

Association Activities

Twenty-five wholesale coal dealers in Norfolk have begun the formation of the **Hampton Roads Coal Association**, to be composed of wholesalers and shippers exclusively, and organized for the purpose of creating a better spirit of co-operation among the members. The organization has in its membership the great majority of the leading coal dealers of the port. The organization is now being perfected.

W. E. Koeppler, of Bluefield, chairman of the Convention Committee of the National Coal Association; C. C. Crowe, assistant secretary of the National Coal Association, and E. C. Porter, in charge of the exhibition of the American Mining Congress, were guests of honor at the first meeting and luncheon of the **Cincinnati Coal Exchange** held this year. They accepted the invitation extended by the exchange to hold the convention and show at Cincinnati, May 14-18, subject to the usual ratification. Because of the fact that the meeting of the American Mining Congress is to be held on the Pacific coast it was felt that their exhibit would be far more advantageously held at the time of the coal convention. In addition it is proposed to hold a Fuel Economy show at the same time. Talks for the Exchange were made by President E. F. Bardin, Colonel Charles Moriarity, Jim Layne and A. A. Liggett.

The tenth annual meeting of the **Logan County Coal Operators Association**, held in Logan late in February, was attended by operators representing nearly every company in the region. In electing officers to serve during 1924, the association named as its head M. E. Kent, president of the Cleveland Cliffs Coal Co., with headquarters at Ethel; C. W. Jones, of the Merrill Coal Co., of Henlawson, as vice president, and H. A. McAllister, of the Logan Mining Co., as treasurer. Elected to membership on the executive committee were M. E. Kent, chairman; T. F. Downing, of the Monitor Coal & Coke Co.; J. A. Kelly, of the Main Island Creek Coal Co.; A. R. Beisel, of the Island Creek Coal Co.; W. R. Thurmond, of the Thurmond Coal Co.; A. J. King, of the Aracoma Coal Co.; R. R. Smith, of the R. R. Smith Coal Co., and C. H. Jenkins, of the Logan Mining Co. The bulk of the session was devoted to various phases of the lake freight-rate case. President Kent stated that "When recognition of the great importance of this issue is brought home to the people who buy coal, we believe that there will be widespread protest against action which would shut our coal out of

the markets of such a large section of the country as is served by Great Lake shipments from the lower lake ports. Widening of the differential as between West Virginia coal and that produced in the Pittsburgh and northern Ohio districts would bring ruinous consequences not only to the operators and miners of southern West Virginia but to the entire community, which depends so largely upon the coal industry for its prosperity."

Industrial Notes

The Fort Smith Spadra Coal & Mining Co., of Clarksville, Ark., is installing new equipment at its mine near Hartman, Ark. This plant will have automatic weighing pan, breaker and steel pan conveyor to screens; is putting in two sets of shaker screens, which give exceptional preparation and also will have picking tables and loading booms. When completed the plant will have jig washers for the small sizes. The United Iron Works, Inc., of Kansas City, Mo., is doing the engineering work and furnishing the equipment.

Howard MacNeal, formerly of the Philadelphia plant of the **Link-Belt Co.**, has been transferred to the Chicago works of that organization, where he will bend his efforts in the promotion of portable loaders, portable belt conveyors and electric hoists.

Edward F. Wickwire was elected a vice-president of the Ohio Brass Co., of Mansfield, Ohio, at the annual election of officers held Feb. 15. He joined the company in 1903 and has been secretary for several years.

Directors of the **Sullivan Machinery Co.** have declared a dividend of \$1 a share, payable April 15 to stock of record March 31.

Obituary

Death removed one of the well-known coal men of southern West Virginia and eastern Kentucky when **E. E. Lane**, of Louisa, Ky., aged 48, president of the Royal Pocahontas Coal Co. succumbed to an attack of acute indigestion at the office of Dr. W. W. Mackey at Iaeger on Feb. 23. Mr. Lane was a native of Sagamore, Mich., but for a number of years had resided at Louisa, Ky., on the edge of the Pocahontas field of West Virginia. He became interested in southern West Virginia mining properties and spent much of his time in that section of the state.

Mr. Lane leaves a wife and three children. Funeral services were held early in the last week of February at Pennington Gap, Va.

Major General James B. Coryell, of Philadelphia, died in that city on Feb. 7, age 69 years. He was president of the Fuel Corporation of America and a well-known figure in the Pennsylvania National Guard.

Alex W. Patton, treasurer of the Patton Coal Co., of Fairmont, died at a hospital there, Feb. 25, following an operation for a sinus affection. Blood poisoning developed. He leaves his wife, his mother, who resides in Parkersburg, and a brother, F. J. Patton, of Fairmont, head of the Patton Coal Co. His former home was in Grafton and later he resided in Newark, Ohio, coming from the latter city to Fairmont three years ago.

Coming Meetings

New England Coal Dealers' Association Annual meeting March 20-21, Boston, Mass. President, W. A. Clark, Boston, Mass.

American Institute of Electrical Engineers, Spring convention, April 7-10, Birmingham, Ala. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

American Welding Society, Annual meeting, April 22-24, Engineering Societies Building, 33 West 39th St., New York City. Secretary, W. M. Kelly, 33 West 39th St., New York City.

International Railway Fuel Association, Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

The American Society of Mechanical Engineers, Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

News Items From Field and Trade

CALIFORNIA

The Falk Corporation, of Milwaukee, has appointed E. C. Myers its San Francisco representative at 320 Rialto Bldg., to handle Falk herringbone gears and Falk-Bibby couplings.

COLORADO

The local land office at Pueblo has been directed by the Secretary of the Interior to offer for lease a tract of public coal land in Colorado comprising 240 acres. The land is in Huerfano County, about 11 miles northwest of Walsenburg, in Townships 27 and 28 South, Range 68 W. Lease for this tract will be at a government royalty of 10c. per ton of coal mined, a minimum investment in mining operations of \$15,000 and a minimum production of \$7,000 tons of coal a year, beginning with the fourth year of the lease. It will be offered at auction to the highest bidder, the exact date for the sale to be announced later by the local land office at Pueblo.

The Peerless Coal Mining Co. has been incorporated in Denver, with a capital of \$200,000, by E. Corbett, S. R. Robinson and T. V. Spacy.

A stiff wage cut is proposed at the Sunshine mine of the Sunshine Coal Co., near Durango. The company has given notice of its intention to reduce on March 31 the wages of miners from \$1.14 to 90c. a ton and drivers from \$7.82 to \$6.50 per day. The Industrial Commission will notify the men of the proposed cut and when their protest comes in hearings will be held to determine whether the reductions are justifiable.

The Colorado Fuel & Iron Co., reports surplus of \$732,029 after fixed charges, depreciation and taxes, for the year ended Dec. 31, 1923, which is equivalent to \$1.68 a share earned on \$14,235,500 of common stock outstanding, after allowing for preferred dividends, compared with a deficit of \$654,944 in 1922. Net earnings, after expenses, amounted to \$4,550,642, compared with \$3,361,327 in 1922.

ILLINOIS

Options on 3,000 acres of coal lands lying between Thompsonville and West End, Franklin County, have been acquired by the W. P. McMillan Co., of Chicago, and it is said that the tract will be fully developed. W. P. McMillan put down the two famous mines of the Old Ben Coal Corporation known as the "Old North" and the "New North," selling them to the Old Ben Corporation later, and has been desirous of getting into the Franklin county fields again.

As a result of a long drawn out wrangle over a question of transfer of coal rights, the Jay Coal Co., of Bethalto, has been placed into the hands of a receiver, Judge Gillham, of Edwardsville, named Harry Kelsey, cashier of the Bethalto State Bank, as receiver for the company.

A. M. Neilson, of Milwaukee, recently paid \$72,000 for the property and equipment of the Illinois & Indiana Coal Co., located at Georgetown. The company owned 550 acres of land near that place and incorporated a holding company in 1920 for \$300,000, which amount was later doubled. Shortly after a \$150,000 bond issue had been authorized, the property went into the hands of a receiver, F. N. Cloyd being named receiver. According to announcements made public, bond holders will receive 50c. on the dollar invested.

The Shed Coal Co. of Marion, a large stripping operation, was thrown into receivership recently and F. D. Borah of Marion, was appointed receiver in the Federal court, to attempt to raise funds and operate the property.

KENTUCKY

Good news was received from Frankfort, Feb. 26, the Kentucky House having defeated the Vaughan coal-tax bill, which originally called for a tonnage tax of 2½ per cent of sales value of all coal produced in the state. This amount had been amended to 1 per cent, but even this figure

didn't attract, and the bill was killed, the House refusing to call it from committee for first reading, the vote having been 43-43, whereas a vote of 51 was needed to bring it out. There are a number of other coal tax bills, but defeat of this one probably will prevent any others from coming out, while the Senate bills are not considered as dangerous.

NEW YORK

The coal corporation of Montgomery & Rodgers, Buffalo, has changed hands. Wesley P. Montgomery will continue under his own name and Elbert Rodgers has opened a new office under the name of Montgomery & Rodgers, having bought the stock of that corporation.

W. H. Bowater, Inc., have removed from 66 Broadway and opened an office in the Cunard Building, 25 Broadway, New York City, the telephone numbers being unchanged.

Camp-Osgood-Sleppy, Inc., have opened an office in New York City. J. G. Allspach, Jr., is in charge as New York sales manager, and Howard W. Ticknor has been appointed New York State representative. Mr. Allspach was associated with the company in its Scranton (Pa.) office.

OHIO

W. E. McEvoy, of the M. A. Hanna Co., Fred Heitzman, of Castner, Curran & Bullitt, and William E. Donnelly, of the Logan & Kanawha Coal Co., have been appointed trustees to liquidate the affairs of the Merrimac Coal Co., of the Dixie Terminal Building, Cincinnati. This company was started over a year ago by M. P. McDermott and his associates with a branch office in Cleveland, which later was closed and McDermott's associates left him one by one. Some lawsuits and other forms of assets are hoped to reduce the total indebtedness which McDermott intends to secure to the creditors through notes, thus taking the burden of the company's losses himself.

Eaton Rhodes & Co., who purpose the erection of large coke ovens and retorts in the Riverside section of Cincinnati, have been brought to a temporary halt in their plans through the interference of the City Planning Commission, which has summoned various members of the firm and others to discover just how much of a "nuisance" can be expected and what plans are made for safeguarding other property adjacent.

The J. P. Burton Coal Co., Cleveland, has opened a new stripping operation at Magnolia, on the Baltimore & Ohio R.R. New equipment has been installed and production will be ten cars a day.

With the resignation of F. A. Binder and F. U. Fisher from the Three States Coal Co., the election of officers has changed its personnel to C. A. Clyborn, president; Frank T. Beazley, vice-president, and J. Coy Pearce, secretary. Its headquarters is in Bluefield with main selling offices in Cincinnati.

PENNSYLVANIA

A state charter has been issued to the Kohut Coal Co., of Homestead, with a capital stock of \$20,000. John Kohut, Homestead, is treasurer, and with J. M. Honse, and Paul Kohut, Homestead, incorporated the company. The purpose of the company is mining, producing, buying and selling coal and its byproducts.

Seward E. Button, former head of the Pennsylvania State Department of Mines, has been made vice president and general manager of the Temple Coal Co., with offices in the Board of Trade Building, Scranton. He was a district superintendent with the Temple company when Governor Martin G. Brumbaugh, in seeking a capable man to head the state bureau of mines in 1918, selected Mr. Button, who was reappointed by Governor William Sproul. He retired from the state position a year ago and returned to the Temple company as general superintendent. For several years he was president of the Pittston Mining Institute. He is also a member of the Engineers' Club of northeastern Pennsylvania.

The sum of \$125,000 will be paid the widows, orphans and other dependents of the thirty-six miners who lost their lives in the explosion of the Barnes and Tucker mines at Shanktown, Jan. 26. The dependents of each of the miners will receive on the average a payment of \$4,096, according to reports filed with the Workmen's Compensation Board by the insurance company with which the mine company carried its protection.

A preliminary report on bituminous coal production in the 2,500 soft coal operations in Pennsylvania in 1923, just issued by the State Department of Mines, shows that approximately 135,000,000 tons was mined as compared with 108,310,000 in 1922. The production averaged 342,000 tons per fatality reported, 405 lives being lost last year as compared with 424 in 1922. None of the fatalities was caused by gas or dust explosions, a record unequalled in the past quarter of a century, according to Joseph J. Walsh, State Secretary of Mines. Fayette county led in production with Westmoreland second, Washington third and Cambria fourth. Three hundred and sixty-eight of the deaths were classed as inside and 37 outside fatalities, rock causing the majority of the inside fatalities. The days worked in more than one-half of the mines were below 180 while the days worked in all of the mines ranged from 115 to 276. Secretary Walsh says that the comparatively few number of days the miners worked was due to over-production not only in Pennsylvania but in all the bituminous states. Only 1912 approaches the record of 1923 in the matter of deaths from gas explosions, for in that year but one miner died from gas. The largest number of deaths caused from gas since 1899 was in 1907, when 277 men were killed or fatally injured by gas explosions. In 1919 there were eight fatalities from explosions; in 1920, nineteen; in 1921, two, and in 1922, 108.

Several distinguished foreign industrial observers and engineers were personally conducted to the Gould Mine, of the Bertha Consumers Co., near Finleyville, while on a recent inspection tour of Pittsburgh industries, by Marshall J. H. Jones, mining engineer and vice-president of the company. One party consisted of five Chinese industrial observers—T. C. Hsi, secretary of the Chinese Chamber of Commerce; Alexander Lee, W. Chang, C. F. Hsu and Dr. Chang Chien, Jr., the last named being the son of the greatest industrialist of China. Another visitor was Leon Rucquoi, a mining engineer of Belgium and a nephew of General Rucquoi. The visitors were much impressed with the simplicity and thoroughness of American mining methods as exemplified at the Gould Mine.

State charters have been issued at Harrisburg to the following: Redstone Limestone & Coal Co., Star Junction, mining and preparing for the market coal and limestone; capital, \$80,000; incorporators, John Branick, treasurer; John Ficik and Mike Branick, all of Star Junction; Westmont Coal & Sand Co., Johnstown, mining, digging and selling coal and sand; capital, \$25,000; incorporators, G. W. Griffith, 109 Barron Avenue, Johnstown, treasurer; L. L. Faust, Windber, and J. B. Huckins, Johnstown.

Bids were opened at the U. S. Engineer Office, Philadelphia, Feb. 27, for furnishing and delivering 15,000 tons of semi-bituminous coal, approximately 12,000 tons to be delivered directly to vessels at coal piers and approximately 3,000 tons to be bunkered into vessels in midstream. For delivery at piers the bids varied from \$4.81 to \$6.23 per ton, and for bunkering into vessels in midstream the prices quoted were from \$5.31 to \$6.58.

In the Sixth Anthracite district 4,372,726 tons of coal was produced in 1923, compared with 2,172,992 tons in 1922, according to the report of Mine Inspector David T. Williams. The services of 7,859 men and boys were required to accomplish the task. There were an even hundred non-fatal accidents and twenty-four fatal accidents.

The Lehigh Coal & Navigation Co., in its annual report for 1923 just issued, showed an increase in revenues of more than \$8,000 over 1922, while operating expenses increased by a shade less than \$6,000,000. Net income for the year was reported at \$3,473,507, after charges and taxes, against \$1,587,024 the year before, or equivalent in 1923 to \$5.93 a share on stock of \$50 par value, against \$2.71 the year before. Revenues in 1923 amounted to \$27,098,022, against \$18,786,431 the year before; expenses \$18,540,690, against \$13,554,734; net revenue after depreciation, depletion and other reserves, \$6,327,707, against \$3,788,207; general expenses, \$221,456, against \$201,887. After dividends,

which in both years amounted to \$2,339,472, there was left in 1923 a surplus of \$1,134,035, against a deficit the year before of \$752,448.

W. W. Gillett having resigned as purchasing agent of the company to engage in other business, **J. E. Nieser has been appointed purchasing agent of the Hillman Coal & Coke Co.** and its subsidiary and affiliated companies, effective March 1, 1924.

The Peabody Coal Co., of Chicago, has completed 100 new miners' houses in the village it is building at its mines near Cramer, and is expected to build as many more during the present year.

Coal companies of Scranton who have announced their intentions of fighting the new valuation of \$800 per foot acre placed on coal for 1924, may have to pay a penalty unless their city taxes, or at least some portion of them, is forthcoming before the appeal is decided in court. It was announced that the coal companies can be penalized under the law if they fail to pay their taxes before the penalty date is reached. City authorities, it is said, are preparing to enforce the law in this respect and regardless of the outcome of the court cases, intend to have the coal companies make a substantial payment on their taxes. According to John H. Jordan, chairman of the Board of City Assessors, there will be no appeals from the coal companies heard by the Board of Assessors. The courts will have to dispose of whatever claims are to be put up by the coal men against the \$800 valuation.

SOUTH DAKOTA

The Scranton Coal Mining Co. has been incorporated for \$150,000 by T. Finnsers and F. E. Oelker of Scranton, Edward K. Mather of Mitchell, S. D., David Hanna, of Wood Lake, Nebr., Frank Schrimpton of Ainsworth, J. F. Schmidt of Scotland, and James Richards of Scranton.

VIRGINIA

The Virginia Iron, Coal & Coke Co., for 1923 reports gross earnings of \$7,918,766 against \$4,354,846 in 1922, and net income, after all expenses and charges for interest and taxes, of \$456,664 against \$575,393. After allowing for regular dividends on the preferred stock, the company last year reported a balance equal to \$2.06 a share on the \$10,000,000 common capital stock outstanding against \$3.25 a share earned on the common stock outstanding at the close of 1922. After payment of dividends last year there was reported a deficit of \$143,146 against a surplus after dividends of \$325,583 in 1922. The balance sheet on Dec. 31, 1923, showed a profit and loss surplus of \$628,890 against \$772,012 in 1922. Inventories were valued at \$1,416,854 against \$1,636,161, cash of \$150,693 against \$194,511, and bills and accounts receivable of \$508,882 against \$196,455. Accounts payable totaled \$8,696, against \$10,278, and unpaid payrolls \$288,801, against \$300,934.

WASHINGTON STATE

The Church Mountain Coal Co. has been incorporated for \$450,000, at Bellingham, by M. T. Hurst, James J. Brady and Charles B. Sampley. The company holds coal lands which may be developed later.

The Cedar River Coal Co., a co-operative concern, has started operating at Landsburg, near Ravensdale.

The 1923 output of coal in Washington totaled 2,946,000 tons, according to the annual report of William R. Reese, chief mine inspector. More than 4,000 men were employed in the industry, producing an average of 3.18 tons per man. The value of the coal at the mine ranged from \$1.41 to \$5.44 per ton. Kittitas County, containing the Roslyn and Cle Elum fields and employing about half the state's total number of miners, produced 1,358,350 tons. King County was second with 663,000 tons, followed by Pierce County, 355,715 tons; Thurston County, 268,000 tons; Whatcom County, 187,000 tons; Lewis County, 113,000. Pierce County produced the only coke of the state—37,600 tons at Wilkeson and Fairfax.

WEST VIRGINIA

In connection with the session of heads of the U. S. Bureau of Mines at Pittsburgh lasting a week, beginning Feb. 28, attended by British mining experts, R. M. Lambie, chief of the Department of Mines of West Virginia, has extended an invitation to the visitors to make an inspection of the mines

of West Virginia during their stay in the United States. The British experts include Henry Walker, C. B. E., chief inspector of mines of Great Britain; Prof. R. V. Wheeler, D. Sc. and W. R. Chapman, M. S. They were sent by the British Government for a conference on mining conditions with mining men in the United States and for the purpose of discussing additional safety measures.

Demonstration of mine-rescue equipment of the Mine Safety Appliance Co., of Pittsburgh, Pa., was held for the benefit of a number of employees of the Pocahontas Fuel Co. at Pocahontas late in February and at the same time employees were instructed in the use of the equipment by Henry Theas, special representative of the company, and by officials of the fuel company. A large number of the men from the different plants of the company went through the gas chamber and put the apparatus to a test. A number of officials of the company were present for the test.

The Sullivan Pocahontas Coal Co. has issued \$1,200,000 first mortgage and collateral trust 6½ per cent serial gold bonds, dated Jan. 1 last, and due serially on Jan. 1, 1925, to 1944 inclusive. The company was organized to consolidate the properties and operations of seven producing companies in the Pocahontas-New River fields. The company owns approximately 2,640 acres of land and its subsidiaries hold leaseholds covering an additional 6,150 acres.

The Gulf Smokeless Coal Co., of which W. P. Tams, of Tams, is president and general manager, has completed the work of installing a complete plant for the removal of slate and dirt from coal by air at the Wyco mine of the company in Wyoming County.

Construction work has been completed on one of the largest tipples in the New River district, to be operated by the Maryland-New River Coal Co. It was placed in operation late in February and will be used in lieu of the two old tipples used by the company at its Rothwell and Smokeless mines the output of both mines being dumped over the one tippie, which is of wood construction and which cost with all equipment for the loading and preparation of coal about \$100,000. The company estimates that it will effect a saving of about \$100 a day through the use of the new tippie.

W. Clark Robbie, general superintendent of the Jamison Coal & Coke Co., in the Fairmont field, will be able to return to his headquarters at Fairmont soon, following an operation at a Baltimore hospital about the middle of February.

The Circuit Court of Monongalia County has granted the application of the Chaplin Collieries Co. for an injunction to restrain the Purslove Mining Co. from mining and removing Pittsburgh coal from the seam underlying the Sewickley vein, owned by the plaintiff "in such a manner and in such a way as to unnecessarily injure the plaintiff and destroy its mine and endanger the lives of employees." Under the terms of the injunction the defendant company is required to "so mine and remove coal underlying the coal and mine of the plaintiff as will not deprive the plaintiff of any substantial support to which it is entitled and not endanger the workings of the plaintiff's mine and the safety and lives of its employees." The injunction will not have the effect of forcing the defendant to suspend its mining activities but it will require the defendant to leave all supports, props and posts standing instead of drawing them, as is usually done when a section of a mine has been worked out.

In changing its name to the **Nuriva Smokeless Coal Co.**, the Trace Fork Coal Co. also announces a change in the name of the post office and railroad station, which will hereafter be known as Nuriva. Officers of the company are H. R. Tribout, president, Tams; W. H. Ruby, vice-president and general manager, Mullens, W. Va.; George A. Butman, secretary and treasurer and R. F. Wildey, assistant secretary and treasurer, Nuriva W. Va.

In order to remove any doubt as to its title to coal lands recently acquired from the Lasher estate in Wyoming and McDowell Counties, the Fordson Coal Co. brought suit in the Circuit Court of McDowell County and that Court has confirmed in a decree the sale of 5,532 acres of the estate to the coal company, the purchase price of \$511,710 to be divided among the heirs.

Adopting the recommendations of the West Virginia Department of Mines, made by R. M. Lambie, chief of the department, after an inspection of the property, the **A. L. Black Coal Co.**, operating in the vicinity of Maldsville, in Monongalia

County, will take steps to flood its mine, cork all means of air entrance and cut out a path behind the mine fire, which threatens to destroy all the coal company acreage, in meeting of representatives of the company, officials of the Department of Mines and representatives of the Warner Collieries Co., of Cleveland, which owns the coal property adjacent to the Black holdings. Water will be pumped from the river through a 6-in. line, the pump to be used having been delivered at the mine. It also is proposed to cut away the earth from the surface down through the Sewickley vein to the Pittsburgh vein with a view to stopping the spread of the fire, even though such a method will destroy considerable coal. In other words it is proposed to strip the coal for some distance in the rear of the burning area. The mine will be closed down entirely until the fire is under control. This fire has been raging since November, 1920.

The Comfort Coal Co. has reduced its total authorized capital stock from \$50,000 to \$5,000. The Westmoreland Coal Company of the State of Pennsylvania and with headquarters at 223 South Third Street, Philadelphia, has been authorized to transact business in West Virginia.

WASHINGTON, D. C.

The U. S. Supreme Court March 3 refused a writ of certiorari which would have caused it to review the suit of the **Braddock Coal Co.**, of Maryland, against David J. Sheehan, of Massachusetts. The verdict of the lower courts awarding \$6,112 to the coal company therefore stands. The suit involved alleged breach of contract for the purchase of 1,000 tons of coal by Sheehan from the coal company.

Official instructions have been issued by the acting director of the Bureau of Mines to all members of its technical staff calling attention to the necessity of exercising great care to confine work to those problems which do not encroach on the field of the professional engineer.

The U. S. Supreme Court on Feb. 18 denied a writ of certiorari sought by the **Piedmont Coal Co.**, of Pennsylvania, and the Ayrshire Corporation to appeal from decisions of the lower courts which had dismissed injunction proceedings to restrain certain creditors of the bankrupt estate of Josiah Van Kirk Thompson from prosecuting suits and exercising liens on several thousands of acres of coal lands in Marshall and Ohio counties, West Virginia. The decision of the lower courts, so far as the injunction is concerned, stands. The Piedmont company, through the Ayrshire Corporation, bought the coal lands from the trustees of the Thompson estate. They contended that the sale was free from liens. When various litigation involving the estate was renewed they sought an injunction to separate the land they had bought from the suits.

A new petition for abolishment of the **Government Fuel Yard** and turning over of all government coal business to local retail dealers will be presented to Secretary of the Interior Work soon. Dissatisfied with rejection of their original petition, presented to the Secretary of the Interior on Dec. 14, local dealers have prepared a new proposal, replying to various questions brought up by Secretary Work's advisers, which they hope will result in securing the government business.

CANADA

Representatives of a number of municipalities of Western Ontario held a conference at London on Feb. 26 to consider the coal situation. A resolution was adopted calling on the Dominion government and the Railway Board to take action without delay to provide cheaper freight rates on coal shipped from Alberta into the Province. Attention was directed to the fact that wheat is hauled at \$7 per ton and it was contended that coal should receive equally favorable rates.

The coal production of British Columbia for January totaled 243,018 tons, an increase of 34,590 tons over that of the previous month. The output of every district was better than that of December, Vancouver Island advancing by 19,653 tons, Nicola-Princeton by 5,174 tons and the Crows Nest Pass district by 9,763 tons. Colliery managers do not pretend to explain the improvement but put it down to vagaries of the trade which cannot always be traced to their precise cause.

William Hart, electrical engineer of the Valier Coal Co., at Valier, has resigned effective Feb. 1. No successor has been appointed.

New Equipment

Steam Turbine-Generator Lighting Unit

A small non-condensing, steam turbine-generator lighting set of unusual simplicity and ruggedness has been developed recently by the Westinghouse Electric & Manufacturing Company for use in oil well rigs, steam shovels, isolated pumping plants, and general outdoor construction work. It is equally applicable for service around the mines, for the generator coils are specially impregnated and parts needing protection are heavily sherardized.

The unit, which is capable of generating 1,500 watts at 115 volts direct current, consists of a single wheel, of the Westinghouse impulse re-entry type, and a specially designed direct-current generator. It is unusually simple in design and substantial in construction, with only five castings and five moving parts. The moving parts are the shaft carrying the generator armature and turbine rotor, two governor weights, the governor spindle, and the valve stem.

NO BEDPLATE IS REQUIRED

The outfit requires no bedplate or foundations, the whole unit being supported

Small Steam-Driven Generator

Automatic speed control makes this outfit particularly suitable for lighting service around coal mines.

ported by feet on the middle casting, which contains the generator inboard bearing. These feet can be secured to any substantial horizontal support with four small bolts, studs, or lag screws. This construction prevents distortion from bolting down or from the expansion of the parts due to heating.

The generator consists of a forged steel frame ring, two cast iron brackets and the usual internal construction as to field, armature and brush rigging. The commutator end is provided with a protective drip-proof pressed-steel cover, which is held in place by two wing screws. The field windings of the generator have the shunt and series windings wound together as one coil, but inside the coil itself, the two windings are entirely separate and thoroughly insulated from each other.

A ventilating fan is mounted on the shaft outside of the rear bearing between the turbine and generator. The air is drawn in through the front cover, through the generator and out through a number of openings in the rear bracket. This fan is guarded to prevent injury to the fan or the operator.

The unit complete is 32½ in. long, 14½ in. wide, and 12½ in. high. Its net weight is 250 lb.

Newly Designed Trolley Locomotive

The Morgan-Gardner Electric Co., of Chicago, Ill., has recently announced its new type trolley locomotive for mining service. The motors in this locomotive are equipped with roller-bearings with heavy overload capacity permitting the slippage of the wheels under all conditions of load. Interpole construction insures sparkless commutation with low brush and commutator maintenance.

The reduction gears are of the single unit type, accurately machined and heat-treated, and possessing the "Wisdom" tooth designed by the Cincinnati Tool Steel Gear & Pinion Co. These gears and pinions are inclosed in a close-fitting gear case and run in transmission oil. The main journal springs are of the semi-elliptical leaf spring type, which gives the locomotive easy-riding and good tracking characteristics. The spring arrangement is also such that all the wheels rest solidly on the track and distribute the weight of the locomotive uniformly.

The brakes are of unusually rugged construction in every detail, overcoming much of the difficulty experienced with the ordinary type of brake. Angle guides hold the shoes in place on the wheels and cause a uniform pressure of the whole shoe upon the tire.

The clearance under the locomotive is unusually large, making operation possible where the track conditions are poor.

A Modern Trolley Locomotive

The designer of this machine has endeavored to incorporate every worth-while feature into the equipment. A detailed

survey of the locomotive shows how successfully this has been accomplished without disturbing the balance.

The valves are of the balance piston type, balanced in all directions and re-

No. 36 Red Giant Drill

This little air drill can be handled by one man for down or side hole reaming and drilling.

quire no pressure to hold them in their seats. Moving but 1/20 of their length and not requiring rocker arms or gears, they take no appreciable power to operate them. The valves are located between the cylinders with very short ports, thus providing air control as close to the cylinders as possible.

It is claimed that the lubrication system is quite economical, the motor being double acting and provided with packing glands, which prevent leakage of air into the crank case. Splash lubrication is used.

Number 11

Doctoring a Sick Industry

FROM a retailer comes a suggestion for satisfying the complaints of the public about the anthracite industry. He may not understand his subject completely. In fact he shows that in some ways he does not by saying in his opening paragraphs "What's wrong? Too many mines. Too many miners. Too much seasonal variation in consumption. Too much railway politics."

Every one knows that there are not any too many mines or too many miners in the anthracite industry. No recognized authority has ever said so. That is true no matter what may be said and rightly about the bituminous-coal situation. As for seasonal variation, every one knows that has not been true for years, though it may come about if peace reigns in the anthracite mines for a few seasons. As for railroad politics, that has not restricted coal production in the anthracite region for years; in fact every one knows the relation between railroads and mines, now nearing an end, has fostered the delivery of coal as fast as it can be mined.

* * *

But sometimes this retailer does not get "beyond his last." As representing the Hackensack Coal & Lumber Co., H. B. Blauvelt doubtless knows the retail trade. He is to be believed when he says in *Printers' Ink*:

Much of the present public discontent arises from poor coal—abominable, unburnable stuff which in times of stress is shipped at outrageous prices by 'snowbird' producers. These are disreputable, illegitimate companies or individuals who ship anything they can scrape together regardless of its grade, and it is this class of 'independents' more than any other who have given the coal industry its blackest eye.

Believe this expert; he knows. "Its blackest eye," mark that! We agree with him.

He suggests that the bulk of the anthracite companies should assess themselves two cents per ton and form an association "for administration, research and advertising purposes" and let the public know that they are selling good coal with a certain maximum impurity. Then he tells the anthracite industry that the fruit growers have similarly combined and have been successful. The public now insists on receiving the trade-marked product of the fruit growers' associations.

* * *

But the fruit growers are of the farmer class and what they can do would raise a revolution if done with coal. A bill is even now proposed to guarantee the farmer \$1.59 a bushel for his wheat and to seize the elevators and mills that will not pay it. That farmers, so far as legislation is concerned, can "get away with murder" is generally conceded.

Coal companies cannot attempt even the most harmless of combinations. Note the relation with the railroads which was fostered by legislation in earlier years

and was popular with legislators and which is now a crime not to be contemplated. But suppose it could be done, there is still the retailer. If coal were sacked and sold in sacks, as fruit is boxed and sold in boxes, the trick might be turned, but coal is shipped in bulk and mixed by the retailer with the "abominable, unburnable stuff" which Mr. Blauvelt excoriates.

The retailer, in short, is the more general offender, for he, it is, who makes the clean product dirty. He even, in some cases, seeks out, aids and abets the "snowbird" operator for his own advantage. It is bold indeed for a retailer to put the blame on the producing end of the industry. True, Mr. Blauvelt may be, and probably is, ethical; some retailers are, but they are not justified in selling "abominable, unburnable stuff" to the consumer.

* * *

Still the problem remains. Rejecting Mr. Blauvelt's plan solves nothing. Let us look at other plans. The public probably would not approve of the companies retailing their own coal. It is easy to realize that the retailers would not like it and they would work effectually on the feelings of the consumer unless they were bought out and well recompensed. And the public would view retailing of coal by anthracite companies as they view transporting of coal by them.

No! if the hard-coal producers are to clear their skirts of selling this "abominable, unburnable stuff," they must have some consumer inspection of coal and then they must have some authority see that coal thus inspected is sold without subsequent mixing with uninspected coal. That is work for independent inspectors, for the public must have full faith in them.

* * *

As for his advocacy of advertising, we would say, "Nothing but true statements in advertising can make it pay." See that good coal gets to the consumer and then advertise the fact. Let the operator be able to say in his advertisement that his coal is inspected, at least in sample, by disinterested parties or by men interested only in protecting the public, that only inspected coal is used in making the retailer's mixture, or that each coal is marketed separately. Then the advertising will do a 100-per cent job, but not till then.

We believe firmly that an advertising job remains to be done, but the product must first be right, and the retailer is perhaps more to be censured than any one for the present "black eye" which is worn conspicuously by all branches of the industry. A campaign just now might be successful, because the coal coming to the market is at its best, but if a strike occurred and a shortage resulted, conditions of earlier years, if not met by inspection, would destroy the effect of the advertising and leave only a sore, disgruntled public.

Black Sheep in Good Families

NOT all the mines of any big company are destined to survive this period of low prices and restricted demand. Some will be closed so that the others can be run steadily. Which should shut down is often quite a puzzle. The high-cost mine may be among those kept running if the coal that it produces is expensive only because of certain inherent difficulties which still will have to be met if the mine is closed down. In most regions if a shaft mine is not pumped it will flood, and sometime or other it will have to be pumped dry. On the other hand, a drift mine in general will drain itself, and it will not be necessary to remove the rail or wire because it will not be submerged.

Still, by and large, the high-cost mines of any large corporation should be closed down, and money should be spent to reduce the cost of the rest. As such mines will run steadily, it will be possible to install the best and most efficient machines. What would be too costly to provide for all the mines can be purchased without excessive strain for the few.

An attempt will be made to get from a few mechanically excellent mines the whole tonnage desired. The best talent in the employ of the company will be gathered at these operations, and we shall see some unusual developments. If under the present stress too many irons are kept in the fire, they all unquestionably will be burned. Every company has its black sheep mines. Now is the time to start weeding them out for the benefit of those that are white.

From the Particular to the General

NO SWALLOW makes a summer but the presence of one such bird sometimes convinces the public that summer is at hand. One dishonest man in a cabinet does not prove that cabinet officers are crooks, but if one be found the public will be sure that there are many more, and good men will suffer with the rest. A charge against one is a charge against all. Because one man has been accused we may be years before we again believe in the integrity of the executive heads of the Government. The probity of no man defends him against suspicion if others with whom he is associated seem guilty of wrongdoing.

Many of us can remember when the Senate was regarded almost with veneration. Today that regard has gone. A few black sheep destroyed it.

A few scandals ruined the railroad business. It is slowly coming back to public esteem. Condescendingly and apologetically some of the large consumers of transportation are supporting the position of the railroad industry, but everything they say has the weakness of defense. No longer is the approval carried by acclamation. Yet in the nineties we boasted of our railroads and they were not as excellent or as mindful of public interest as today.

But that is not strange for the public makes almost everything unanimous. When anything is regarded as praiseworthy it is dangerous to attack it. When the majority swings the other way it no longer can be defended. The public never paints its pictures in subdued colors. Consequently care must be taken lest a few flagrant examples upset public confidence.

The coal industry, like other industries, has had its crooks, men who used it for a while to make money and left it when it ceased to promise excessive profits

and when the market once more became discriminating. A handful of wilful men spoiled our foreign coal trade and now foreigners are not anxious to take the risk of buying American coal. We cannot afford to leave such matters to chance. Good business principles demand that something be done to prevent the sale of coal that has been adulterated with slate or has been sold from a dirt pile without first being washed.

Now, in this time of a decline in public interest in coal, can be found a chance to clean house. It might be presumptuous to insist that any particular make of broom should be used for that purpose. It might be the U. S. Bureau of Mines but perhaps the U. S. Chamber of Commerce or the American Engineering Council would be better, but whatever it is, a broom is needed to sweep the industry clean at all times, especially in times of stress, of those concerns who load down the railroads with rubbish and give the consumer coal he cannot burn or can burn only with difficulty.

We Have Some Heroes

AND so far, after all, the world's heavyweight knock-down, drag-out champion is not going into coal operating. Mr. Dempsey has decided not to invest his money in the Great Western Coal Mines Co., will not help develop several thousand acres of Carbon County, Utah, coal and have a new mining town named after him n'everything. How disappointing! Here we were, all set comfortably in ringside seats waiting for the gong. We wanted to see if the human pile driver could "take it." Nobody knows yet. Mr. Dempsey never met anything or anybody who could administer "it."

When the go with Battle Ax Coal was scheduled and duly advertised by Manager Jack Kearns with a care-free announcement that "me and the champ" had decided to invest in Utah coal and become great operators, there was some assurance that Mr. Dempsey really was a fighter. He wasn't afraid of old Battle Ax, the greatest meat chopper of them all. He really was willing to go in there and show the world that he could "take it." We crunched our peanuts and whistled and stamped our feet and bought another bottle expectantly. But now the Roman holiday is off. And we still don't know whether Dempsey can "take it."

But we know a lot of coal operators who can. Old Battle Ax Coal has mauled hundreds to a pulp and has draped thousands over the ropes, broken in spirit and bank account. But in every coal-mining field in this country are men who can "take it." Old Battle Ax hasn't maneuvered *them* into operating properties that have no economic excuse for existence. Their footwork is too good for that. His clever feints haven't tricked *them* into operating and marketing practices that look good for today but which take no heed for the future. His horrible grimaces haven't frightened *them* into spinelessness in their dealings with labor.

Although old Battle Ax has landed many a vicious jab to the wind, these men are always in mental and physical fighting trim and they saved their money when they made it. They are the men who know how in a bad round, to trim their mine costs with good management and machinery and "cover up" during a period like the summer of 1924, when the Battle Ax will do his worst—hitting only their elbows and shoulders. They can "take it." And the time will come when they will make old Battle Ax "take it" too.

Men Who Recovered Alden Mine

Fire, Largely Isolated by a Fault, Is Successfully Sealed by Men in Oxygen Breathing Apparatus

Sickness of Workmen and Near Fatalities Lead Company to Suspect Fire in Abandoned Workings—Tests Showed Increasing Percentage of Carbon Monoxide—Difficulties Encountered in Sealing Off the Fire

MOST dreaded of all mine disasters is a fire, particularly in the underground workings. No two mine fires are alike either in their development or in the extent of area covered. Fire can be fought more readily in the live workings of a mine than in an abandoned section, because in the former case the firefighters are better acquainted with the controlling conditions than they are likely to be in the latter. Fortunately, circumstances frequently favor the isolation of a fire and prevent its spreading to other sections of the mine. Physical conditions in anthracite mines often make it necessary to lay out a mine in separate and isolated sections or districts, and in this case a defense is prepared almost without intention against the spread of a mine fire. Nevertheless in the planning of a mine, due thought must be given to the possible occurrence of fire in the workings, particularly if the coal is relatively free-burning and friable or gas is present.

BAD AIR NOTED WITHOUT ANTICIPATION OF FIRE

A well-designed mine plan will take into consideration the ready isolation of each section of the workings, will guard against possible danger and prevent the destruction of the entire mine if an accident occurs in any one section. The failure to do this has often proved a great handicap in the handling of a fire in the

workings, and necessitated the flooding of the entire mine where this might have been avoided with proper care in the planning of the mine.

During the latter part of December, 1922, some men engaged in putting in an engine foundation in a certain section of the Alden Coal Company's mine, at Alden, Pa., came out several times complaining that the air made them sick. This happened at infrequent intervals every three or four days. The occurrence, however, caused little suspicion of fire in the mine and no one suspected any such misfortune until mine inspector Joseph J. Walsh detected traces of carbon monoxide in samples of the air he had taken.

About the same time two men at work in that section repairing stoppings, building mine doors and timbering, were overcome and nearly lost their lives. Knowing the air was bad, the inside foreman had cautioned the men to be careful. His anxiety for their welfare led him frequently to the place, and this proved the means of saving their lives. On such a visit the foreman found one of the men lying at the side of the road in a seeming stupor. The gas had rendered him delirious, and when the foreman roused him with, "Get up and get out of here," the fellow replied, "Take those rails off my legs so that I can get up."

The other man was found with his hammer raised in the air, in readiness to nail up a board. So strong

and firm was the man's grip on the hammer that it could not be removed from his hand till he had been taken to the outside of the mine and sent to his home. Both the men owe their lives to the watchfulness of the foreman, and the incident shows the speedy and fatal effects of carbon-monoxide gas when men are exposed to air containing only traces of it.

Inspector Walsh sent the air samples that he had taken in the mine to the U. S. Bureau of Mines where his results were corroborated. The question now was, whence did the gas come? The gangway in which the men were laying an engine foundation was a return airway from a slope that had been idle for nearly two years, for owing to a heavy squeeze, the workings from it had been made inaccessible.

A gasoline motor was operating in a tunnel from which this gangway had been driven. Naturally, the first thought was that the carbon monoxide in the air was generated by the exhaust from this locomotive. The result was that the machine was promptly taken out and replaced by a storage-battery locomotive. Work was discontinued in the gangway, the men withdrawn, and the place temporarily barricaded. The circulation of air in that section was increased "to sweeten up the workings," as Jack Morris, the foreman, expressed it.

The place was then left standing for about ten days when several more air samples were taken for analysis. These and others taken several days later showed that the percentage of carbon monoxide was increasing rather than decreasing as had been expected. It was then definitely decided that coal was on fire somewhere within that section of the mine and the problem was to locate and extinguish it with as little delay as possible.

This conclusion was made certain by the fact that tests taken in the several intakes gave no indication of the presence of gas either by the use of the carbon-monoxide detector or by the analyses made of the air samples taken at those points. On the other hand, both the carbon-monoxide detector and the analyses of air samples taken in all the returns from that section showed the presence of the gas. Furthermore, the tests also showed a low oxygen content in the return air. Indeed, at times, it was impossible to work in that airway without the use of breathing apparatus, and the Koehler lamps refused to burn.

DID NOT ATTEMPT TO USE FAULTY APPARATUS

The rescue apparatus at the colliery consisted of five sets of breathing apparatus, one high-pressure oxygen pump, a number of oxygen cylinders and nearly 100 lb. of caustic soda. This equipment was supplemented by fourteen sets of more modern breathing apparatus, eight sets of which were purchased by the company, as the apparatus on hand was old and unreliable.

For the work in hand, twelve trusty and experienced mine workers were chosen and given training for three or four days in the use of the breathing apparatus. This was done under the direction of Jesse Hensen, whose services were kindly placed at the disposal of the company by the Bureau of Mines. The twelve men were divided into two working crews, one being placed in charge of Mr. Hensen and the other in that of James Jeffries, the company's fireboss.

In Fig. 1 is shown the larger portion of the mine operated by the Alden Coal Co., which adjoins on the west the property of the Susquehenna Collieries Co. The map shows the location of No. 2 shaft of the Alden

Fig. 1—Fire Area at Alden Coal Co.'s Mine, Alden Station, Pa., Was Confined to Slope in Cooper Bed

Recovery was made by first sealing up the intakes at points marked S and T followed by the placing of seals on the return at A, B, C and D. Water was directed into the sealed area and thus the temperature was lowered, though when the seals were being placed the return was at a temperature of 156 deg. F.

The roadway from No. 2 shaft to shaft No. 1 is not straight but takes a right-angled turn near No. 1 shaft just as it does near No. 2. In consequence No. 2 shaft is almost exactly north of No. 1. This fact will aid in allocating the cross-section shown in Fig. 2.

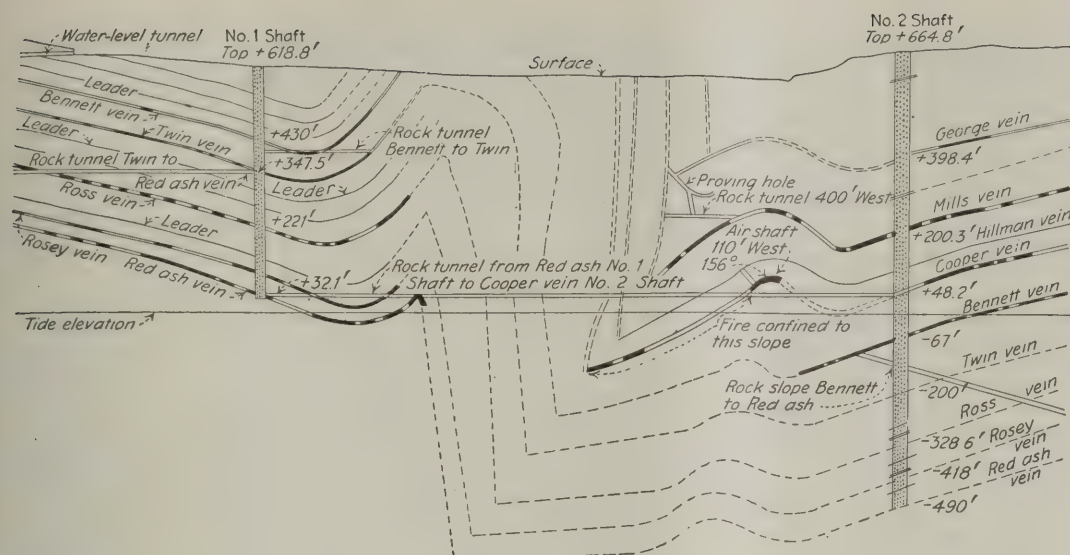

FIG. 2

Cross-Section

This shows how a heavy roll makes the bed almost vertical adjacent to the fire area. In fact the bed has been overthrown or lifted through an angle of over 90 deg. This fault, or should it not rather be termed "fold," aided in preventing the fire from spreading toward the South. Note the rock tunnel from the Red Ash bed at No. 1 shaft to the Cooper bed at No. 2 shaft. The tunnel is that shown in Fig. 1 as the tunnel to No. 1 shaft.

Coal Co., and the position of the tunnel projected from the old No. 1 shaft on the south. It also shows approximately the section of old workings in which the fire was assumed to be located.

START SEALING FIRE IN INTAKE OPENINGS

The intake current circulating through these old workings is indicated by the arrows shown in the gangway driven to the west of this tunnel. Following the intake air, the workers first started the building of a number of substantial stoppings to close the intake end of the section containing the fire. On the map these stoppings are indicated by S. All the stoppings were thus closed but one, which contained a trapdoor marked T, by which the quantity of air entering the section could be controlled, thus avoiding the formation of an explosive atmosphere within the inclosed area.

At the extreme west end of the fire section, it will be observed that a large door was erected in a tunnel which cut through an anticlinal in the Cooper seam. The purpose of this door was for the further regulation of the air entering that section. Much time had been consumed in investigation and preparation for the work, and the building of the intake stoppings was only started April 20, 1923. It was slow and tedious work. Boards, bags of sand, cement, ashes and water had to be carried from the base of supplies, marked X on the map, a distance averaging more than half a mile, much of the way being through old workings that were well nigh impassable.

The physical features in the Cooper seam were such that this section of the mine was cut off on all sides by two faults that isolated the section from other workings, a condition that greatly assisted the work of isolating the fire. Moreover, a large barrier pillar of virgin coal had been left for the protection of the two properties adjoining.

Although the work of building the intake seals was arduous, it was not performed under as trying conditions as that of building the seals on the return end of the section. As indicated on the map, there were but four of these openings to be closed. These are marked A, B, C and D. The approach to the last two openings on the east side of the tunnel is indicated by a line of crosses. The advance was made in face of difficulties more trying than any yet encountered. It called for the exercise of the highest degree of courage and devotion to duty, but the men were not found wanting.

At times the temperature in the return reached 156 deg. F. Tests of the mine air showed 8 per cent of methane and an oxygen content of 3.7 per cent. Under these conditions, it was necessary to carry compressed air along the passageways to cool and dilute the atmosphere and make it possible for the men to work. The way led up an old chamber, over an anticlinal and down another chamber dipping 45 deg. to a gangway in old workings made twenty-six years previous. The fireclay roof and the rotten timbers were enough to tax the endurance of the bravest workers, but no one asked to be relieved, though many were gaunt and thin by reason of their experience.

The last opening, at D, was reached Sept. 8 and the

Fig. 3—Some of the Fire Fighters

Heavy grades, bad conditions such as are found in abandoned places, absence of track and finally bad air and intense heat made the work of recovery almost insuperably difficult, but the men knew neither fear nor weariness and the work was successfully performed.

sealing completed six days later. The loyalty of the men reflected the confidence they had in their foreman, Jack Morris, who was always ready with a word of encouragement and appreciation throughout the nine months required to complete the work.

The tables herewith show the analyses of air samples taken in the current returning from openings C and D. The samples taken previous to Sept. 11, from the opening marked D were from a broadcast return. This was owing to the difficulty of near approach to that opening, as will be understood from the account given of the work of sealing that opening, which was started Sept. 8, but practically finished Sept. 11, the work being finally

Where the Miner Waits for Cars—and More Often Doesn't Wait

How Miner and Manager, Each with His Immediate Ends in View, Hamper Coal Production

Loaders Without Cars and Managers With Their Men Hurrying Home Early Make a Mine a Place of Deplorable Inefficiency—
Miner's Other Duties Lighten the Monotony of Shoveling

AS A RULE the miner does not confine his efforts exclusively to shoveling coal. While he should be an adept in the use of the shovel, necessity demands that between filling successive cars, he vary his labor. Thus he drills holes, charges them with explosive, picks down coal, sets props and gobs refuse. This variation in employment materially relieves his muscles and gives him a diversity of occupation to vary the monotony of shoveling.

The miner and the management in most mines—and this applies to company or daymen as well as to those working on tonnage—co-operate less effectively than in most other industries. The miner fails to receive the necessary cars in which to load his coal. The men upon whose labor the miner depends fail to co-ordinate their work with his. Supplies are not furnished him as needed. No instructions are given him to assist him in performing his work, nor—and this is of even greater importance—is any analysis made of conditions and methods to find out how his work can be made as easy as possible. Left thus without support the miner is rendered irritable. Beyond question this lack of co-ordination is one of the major reasons why the miner is habitually dissatisfied with his life. As has been shown in previous issues of this report a miner may readily lose from one-fifth to one-third of his daily earnings through failure of the management to supply a needed mine car. Even supposing that this failure

occurs only occasionally, the depressing effect upon the man is inevitable. When he sustains financial loss also because of inferior supervision, the aggravation arising therefrom is equally great.

The actual time spent by miners within the workings and also the hours of quitting work are shown for two different days in two mines in Figs. 1 and 2. These are presented merely as illustrations and are not intended to represent average conditions. Similar records made in other mines where, as will be noted, relatively full time is shown, are fairly representative of operations that are working only a few days a week, and where consequently miners are anxious to earn all they can each day.

Fig. 2 is more nearly representative of either full-time production or particularly good physical conditions where tonnage rates permit large earnings. This chart is the result of observations taken where a thick bed of coal with good roof and opportunity to make good pay prevailed. In this mine, for example, the miners were loading, on the average, at the rate of about 15 tons per day with a union rate of 84c. per ton. They are accustomed to earning therefore, on days when they work, about \$12.60.

In Fig. 2, the time of the loaders and machine cutters leaving the mine is given separately. It will be noted that not only about half the miners left the mine before the end of the 8-hr. day, but that the cutters remained in the workings a much shorter period. This indicates an extremely uneven apportionment of work between the two groups of men. It is interesting and valuable in this connection, to state what reasons were given

Seventh installment of report on "Underground Management in Bituminous Mines" made by Sanford E. Thompson and associates to the U. S. Coal Commission. Previous installments may be found in Vol. 24, pp. 691, 733, 773, 811 and 845 and Vol. 25, p. 137. Other sections of this interesting report will appear later.

by the miners for leaving their places early. Though it was, of course, impossible to verify the truth of the miners' statements, the fact that 29 cutters left the mine before the end of the day because there was no cutting to be done and 80 miners left during the same period because their places were not cut is a specific example of the failure of the management to correlate the work of these men. In many instances, this lack of co-ordination is greatly augmented by local rules or customs limiting the number of working places assignable to each machine.

The record of more than 63 men leaving the mine because they had earned all they wished to earn that day represents a condition existing in various degrees in most of the mines visited. It arises in large measure from the fact that existing piece rates for coal mining have been based upon the consideration that the mines only operate part of the year and that when they do work conditions are not such that the miner can work steadily throughout the day. In periods of steady work at the mine the miner is not anxious to earn maximum pay. Consequently, if able to work continuously throughout the morning, the miner can earn a wage which will satisfy him in far less than the 8-hr. standard day, and he will leave the mine when this is accomplished.

Fig. 3 is from the records of a day's work in a mine where 39 miners were employed. This diagram shows the time at which each miner entered or left the operation. In the upper portion of the chart also will be found the length of time that each miner worked. This time, in general, is longer than is the case in most operations, this mine being on a profit-sharing basis.

Elimination of some of the high-cost mines, provision of a more regular car supply and storage of coal by the consumer might reduce intermittent shutdowns of the mine and level out the seasonal demand, to such a degree that the miner being able to earn enough in a few hours would so shorten his working day as to interfere seriously with the proper management of the mine. The operation of the mine cannot be planned so as to give the men an opportunity to work continuously while in the mine unless the miners show a spirit of co-operation. This, however, is a matter of education, not only of the miner, but of the management also, and not until both parties realize that their prosperity and success are interdependent, will it be fully accomplished.

Although lack of time prevented an analysis that would give data of statistical value, the detailed reports charted in Fig. 4 of a day's work performed by three loaders in three different mines located in different fields, is of interest from the standpoint of mine management. It shows the kinds of delays and changes in work that with many variations in detail and degree

Fig. 1—How They Run Home

Percentage of loaders and cutters left in a mine at certain hours of the working day. Some loaders hastened back to lunch apparently and some of the cutters went home so early in the afternoon that they had to wait for their afternoon tea.

are common to all bituminous mines. This will be evident from a study of this chart.

Each division in the vertical columns represents not a sequence of operations, but the sum of all the periods throughout the day devoted to the same operation. Thus, for example, the lower section is an accumulation of all the time spent in shoveling, while those designated as "waiting" are the summation of all the short delays occurring throughout the entire day.

These data were made up from complete stop-watch observations taken in each working place. The two left-hand columns represent a complete cycle of work from clean-up to clean-up in each mine, in a place where two loaders were working together with two rooms available. The right-hand column represents pick mining; that is, none of the coal was cut by machine. The time lost during the day noted in the right-hand column, where the unnecessary time lost was more closely analyzed than in the other two, should be carefully inspected.

The time actually spent in loading appears relatively short, but this does not represent the total time necessary to the filling of cars, because some picking was done while the car was being loaded. Furthermore, the time lost while waiting for cars would not all have been devoted to loading, had cars been available.

Being based on observations of the work of three men, each for one day, these diagrams are not intended to illustrate average or even representative conditions, neither do they portray any particular part of the miner's work in its proper proportion to the others. These diagrams are given simply as illustrations of the nature of the work a loader has to do and the time spent on the individual operation in the three cases noted. The studies depicted were made with the co-operation of the miners themselves, who assisted the observer by furnishing information concerning the various operations.

In studying the variation in time spent by miners in loading their cars after they have been received, Fig. 1 in the article of Nov. 29, 1923, p. 811, is instructive. A miner will frequently stop loading and perform other work which more wisely might be done after he has

Fig. 2—Record of Return Home at Another Mine

Here some cutters and loaders left quite early. One cannot but surmise that the loaders found places uncut and the cutters' places not cleaned up. Twenty-nine cutters at this mine said they left it because no cutting remained to be done, and eighty loaders said they went home because no places had been cut for them.

finished his car. If a miner was accustomed to seeing cars delivered on a schedule he would begin to realize that he is a cog in a smoothly running machine and that failing to fulfill his part, will throw the whole mechanism out of adjustment.

Every hand operation performed in the industry can be executed in either a difficult or in a comparatively easy manner. Certain miners were observed who, under fairly difficult conditions, were handling their shovels with remarkable ease and deftness. One man, working in one of the seams visited, who, because of the thinness of the bed, could not stand erect and who had a comparatively small space above the side of the car, was shoveling with apparent ease and actually faster than any other man observed. This miner threw shovelful

Fig. 3—Time in Mine of Thirty-nine Men
The upper chart shows the time in the mine and the lower chart the entering and leaving time of each individual.

after shovelful of coal against the roof from whence it caromed into the car.

One of the major functions of industrial management is now recognized to be the training of operatives to do their work in the best and easiest manner. It has been determined, for example, that if the shovel is handled in a certain manner the most favorable leverage and the easiest action will be attained.

In coal mining, therefore, there is opportunity for an analysis of the miner's work which will determine such details, among others as the best and most economical height and length of throw, the manner of handling the shovel, the procedure that should be followed in filling a car, the arrangement of the track and the proper location of the car in the working place. After standard practices have been established, the loader should be instructed in them and taught to do his work in the easiest manner. Similar analyses will be found of practical value for the operations of drilling, setting props and performing various other tasks of a more or less routine nature.

Operators may object that such studies will accrue solely to the benefit of the miner and that consequently they cannot afford the expense needed to establish the best method of working. This, however, is a narrow viewpoint, and experience has shown that it is not only good policy to aid a fellow man, but that such studies as have been outlined redound to greater harmony in the relations between employer and employee and result

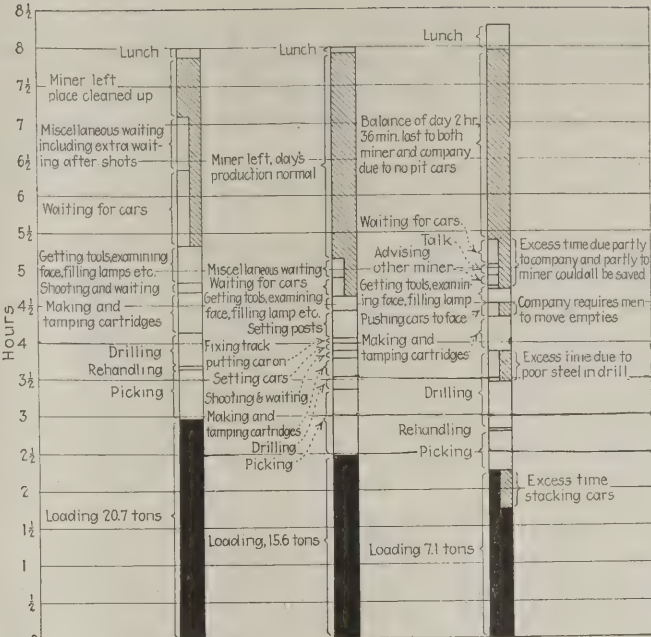

Fig. 4—Record of Three Loaders in Three Mines
What a short time is given to loading is made quite clear by the black portion of the three columns. The hatched portion shows the time lost unnecessarily; either the miner was waiting or had gone home, or was delayed by moving empties, or by poor tools, the waiting period being hatched narrowly where the fault was lack of co-ordination rather than absence from the mine. Note also the loss of time due to building up the sides of cars with lump coal.

in a reduction in the actual unit cost of production. Many mines are working two eight-hour shifts daily and they have thereby effected an appreciable reduction in the cost of mining coal. The change has saved overhead and much dead work. In one of these instances, it is true, the double shift temporarily has been discontinued because an insufficient area had been developed and the operation could not be maintained without pushing the development work more hours than the rest of the mine. Cutting machines are run during a second shift in some mines in which the loaders and company men are on single shift only.

The effect of two-shift work should be carefully studied in every mine from the standpoint of economical management, equipment, development and personnel.

Fig. 5—Lots of Coal Ready and No Car in Which to Put It
The relation between miner and operator is a loose one. The price per ton loaded is about the only tie. The miner loads if he wants to and goes home if he doesn't want to load. The operator provides him with cars on a somewhat similar basis. Neither miner nor operator puts himself out to accommodate the other.

Wetting Down Colorado Mines Is a Real Problem

Low Humidity in That High and Dry Region Makes Dust a Serious Menace—C. F. & I. Co. Humidifies with Both Live and Exhaust Steam and Sprinkles Lavishly

IN THE high and dry region on the eastern side of the Rocky Mountains, many a mine makes no water at all. The result is that at such mines air humidification and other methods of protecting against dust troubles are given most careful attention by operating men. The methods used in such instances by the Colorado Fuel & Iron Co. were explained Feb. 14 to the Rocky Mountain Coal Mining Institute at Denver by R. L. Hair, the company's division engineer at Trinidad, Colo.

Mr. Hair showed how live steam is used both to heat intake air by the use of banks of pipe coils in the mouth of the incast and for further humidification by discharging it into the air stream through perforations in the pipe line 100 ft. inby. Low-pressure steam in great quantities is exhausted into the air stream about 225 ft. in. Atomizing sprinkler heads every 500 ft. leading from water pipes running through all entries carry the humidification deep into the mine.

ROOF, WALLS AND ROADWAYS WETTED FREQUENTLY

At 125 ft. intervals there are hose connections on the water pipes and a man with a piece of hose frequently washes down roof, walls and roadways. Empties are sprinkled on their way into the slope and loads on their way out. And to make certain that the quantity of loose fine coal through the mine is kept down to a minimum, the night shifts load it out frequently. Mr. Hair's paper was as follows:

"Though the annual rainfall in Las Animas County, Colorado—that part of the state with which my paper deals—in 1923 was 26.85 in., the normal yearly rainfall is only about 17 in. The moist warm air which leaves the Pacific Ocean headed in our direction deposits its vapor in the mountains as rain or snow, and when it reaches us in the foothills on the east side of the range,

it is descending and its temperature increasing. In consequence, it is prepared to take up moisture rather than to deposit it. So for our precipitation, we must depend principally on the moisture in the winds from the Atlantic and the Gulf of Mexico.

"Temperature and humidity readings taken at the surface at several of our company's properties last month by Robert McAllister, the company's mine inspector, are as in Table I.

TABLE I—TEMPERATURES AND HUMIDITIES IN LAS ANIMAS COUNTY, COLORADO, IN JANUARY

January	Temperature Degrees F.	Humidity Relative Per Cent
3	37	53
7	40	43
8	39	21
9	36	60
11	37	46
21	35	83
22	44	30

"The average temperature for the seven days was 38 deg. F., and the humidity 48 per cent. This means about two gallons of water was contained in each 100,000 cu.ft. of air. Readings in the return air during the same periods were as in Table II.

TABLE II—TEMPERATURES AND HUMIDITIES OF RETURN AIR FROM MINE

January	Temperature, Degrees F.	Humidity Relative Per Cent
3	65	100
7	62	100
8	61	100
9	65	100
11	65	100
21	66	100
22	60	100
Average	63 F.	

"At this temperature and humidity, about eleven gallons of water are contained in every 100,000 cubic feet of air. Assuming that this quantity passes per minute—about the average quantity at each of our mines—and assuming the temperature and humidities as stated, about 13,000 gallons of water would be ex-

Absence of Water in a Mine Is as Distressing as an Excess of It

These drawings represent what is done in Colorado Fuel & Iron Co.'s mines from slope mouth to side entry to reduce the ever-present danger of dust explosion. An even temperature of intake air is maintained by coils through which live steam

passes to be vented into the air stream 100 ft. inby from the air intake. Low-pressure steam from the fan engine exhausts into the air stream about 125 ft. further in. The mine is watered on the entries by atomizing sprays every 500 ft.

Roof, ribs and roadways are washed down frequently from hose connections every 100 ft. Loads are sprinkled on the way out and empties on the way in. Lastly, night men clean up slack dropped along haulage ways.

tracted from the mine each 24 hours. If no vapor is applied artificially, the under-saturated intake air must get its moisture from the dust on the walls, roof and floor of the mine, and the drier the dust is, the more it is to be feared.

“What we try to do is to heat the air at the mouth of the mine to the required temperature and give it all the moisture it can carry, before it proceeds on its way through the mine. In many cases, we raise it to a temperature higher than the mean temperature of the workings, so that its moisture will be deposited on the walls, roof and floor. By the application of plenty of water under a strong pressure on the roof, sides and roadways, the dust is moistened so that it will ball in the hand. We believe that dust thus thoroughly wetted will not propagate an explosion.

AIR PREHEATED BEFORE IT IS HUMIDIFIED

“The system practiced by the Colorado Fuel and Iron Co. for wetting the mines and humidifying the air begins by a method of preheating the air to the mine temperature and humidifying it. Radiators consisting of 1-, 2- or, even in rare cases, 4-in. pipes are lined along each side of the intake air course. Coils are oftentimes placed along the roof also. These are from 75 to 125 ft. long, according to the radiation desired. They are usually heated by live steam.

“The exhaust steam from the fan engine is carried into the intake air course, preferably a short distance beyond the radiators. This not only supplies vapor to the air but assists in raising its temperature. This steam is supplemented by fine sprays placed along the entry at intervals from 25 to 500 ft. depending upon conditions.

“The second precaution we take is to load up fine slack and dust along the roadways, and the third is to sprinkle profusely. Different types of cars distribute fine slack along the roadways, which is ground up by the traffic of men, mules and cars. This coal is loaded out at convenient times and the entire entry sprinkled by hose under a water pressure of 50 to 75 lb. With valves every 125 ft. one man, carrying 25 ft. of hose, can sprinkle 4,500 ft. of entry in an 8-hour shift.

“Each string of empty cars is thoroughly sprinkled by a heavy spray on each inbound trip from the tippie. This prevents the dust from the cars being picked up by the air current or sifting out through the cracks onto the roadway. Every trip of loaded cars is likewise sprinkled when leaving the partings.

“The average quantity of water applied per day, at each mine exclusive of exhaust steam is shown in Table III.

TABLE III—WATER SUPPLIED FOR HUMIDIFICATION OF MINE	
	Gallons
7 hours sprinkling by hose at 25 gallons per minute.....	10,500
20 fine sprays working 4 hours per day at 3 gallons per minute.....	14,400
Water sprayed on trips at partings.....	500
Total.....	25,400

“Our company installed during 1922, over 72,000 ft. of sprinkling lines of 1-, 2-, and 4-in. diameter in seven coking-coal mines of Las Animas County. The extensions for the year 1923 were: 20,980 ft. of 1-in., 27,279 ft. of 2-in., 120 ft. of 3-in., 5,665 ft. of 4-in. pipe; besides 1,749 ft. of ½-in. and 1,444 ft. of ¾-in. pipe, making a total of 57,237 ft. of pipe of all sizes.

“The cost of labor and supplies for humidification and sprinkling for the year 1923 at seven plants totaled \$34,400 or 0.021 cents per ton of coal mined.”

The Miner’s Torch

Oh, Doctor! Doctor!

A COMPANY attorney finds in trying a case that the testimony of a company physician has little weight with a jury, and he warns all of the operating officials to profit by the experience and not let the company officials get too close to the doctor.

A camp physician who has the reputation among the men of rushing all of his patients back on the job, especially when these men are drawing sick benefits, moves yearly if his job happens to be one where an annual election is the basis of his contract.

Occasionally, we find camp physicians who could qualify as politicians of the first rank; if they would confine their efforts to keeping the men lined up for the yearly election, all would be well but unfortunately, they are sometimes induced to exert leadership that conflicts with the authority of company officials, and then things begin to happen.

We have considered a few of the “hands off” arguments about the company doctor. Now forget these and look at the matter from another angle.

If an employee is injured, and for lack of proper medical attention, loses two months’ work when he should have been back on the job in two weeks, his employers may have suffered a greater financial loss than the employee’s family, even though he did not receive accident insurance or any other kind of compensation. All well regulated companies keep a stock of repair parts on hand to take care of breakdown jobs and for the same reason have understudies, as it were, to take the places of men disabled by accident. But keeping a stock of repair parts up to date is quite a simple matter in contrast to having efficient trained men on hand—men ready to take the place of anyone suddenly disabled.

The contrast can be carried still farther. A piece of machinery generally has its maximum value the day it is put to work, and beginning with that day, it deteriorates in value daily until it is finally discarded. A human machine renders minimum service to a company the day it is put on the job and if it is a normal human it becomes more and more efficient day by day and does not reach its maximum for many years.

Some of our mining companies have been slow to realize the advisability of co-operating with the camp physician; the facilities offered some of these physicians in comparison with the facilities possessed by the average cross roads veterinarian. I have seen offices designated “Doctor’s Office” that would inventory something like this: one cot, three chairs, one water bucket, one first-aid cabinet, size 2 ft. by 1 ft. by 6 in. I almost overlooked the “Safety First” calendar.

DOWNWARD TREND UNDER SOVIET RULE.—In 1917, the Donetz District in Russia produced 27,365,000 tons of coal. In 1918, the production under the chaotic conditions fell to 9,765,000 tons. In 1920 under Sovietism, the output had fallen to 5,017,000 tons, but in 1921, a slight improvement was noted, the production being 6,408,000 tons.

Accidents Add Four per Cent To Operating Cost*

To Losses for Compensation Must Be Added Those for
Delay in Operation, Decline of Morale
and Labor Turnover

BY SUB-COMMITTEE ON EDUCATION

Industrial Relations Committee
American Institute of Mining and Metallurgical Engineers†

TAKEN solely as a matter of dollars, the cost of accidents in mining in the United States, and, therefore, the cost to the individual mining company, is larger than any item on the books excepting direct labor payroll. Practically every mining state, within the past eight years, has introduced some form of workmen's compensation insurance. Of these states, the recent report of the U. S. Coal Commission says, "Competitive insurance under state control, as in Pennsylvania, with schedule and experience rating to evaluate individual mine hazards has given the best results from a safety viewpoint. Furthermore, Pennsylvania, of all the mining states, has the most complete information and analysis of its mine accidents. Therefore, the accident experience of Pennsylvania will be taken as a basis for the statements in this report.

The present basis of rates for compensation insurance under the Act, in the bituminous mines of Pennsylvania is \$2.35 per \$100 of payroll. Estimating payroll as 70 per cent of the total cost of operation, 1.65 per cent of the cost of operation is for accident insurance. In cases of substandard conditions at a mine, the rate may be as high as \$3 per \$100 of payroll and thus 2.1 per cent of the total cost of operation. In cases where most of the substandard conditions have been removed and the accident frequency reduced, the rate has been as low as \$1.30 per \$100 of payroll, or 0.91 per cent of the total cost of operation. The difference in cost between these extremes at a mine employing 500 men would be about \$17,000 per year.

LOWEST ACCIDENT RATE IS IN PENNSYLVANIA

The bituminous mines of Pennsylvania have the lowest accident rate of any group of coal mines in the United States, and probably lower than any group of metal mines. In consequence, the direct cost of compensation insurance is higher in most other districts. The insurance covers, however, only deaths by accident, and injuries where the man is disabled for more than ten days.

Statistically, of 151,022 full-time 2,000-hr. workers employed in the bituminous industry of Pennsylvania, taking an average of the years 1918 to 1922, inclusive, 414 per year were killed and approximately 10,446 injured severely enough to receive compensation. The average time lost by these temporary compensable accidents was 86.2 days, or a loss per year of 899,958 man-days. This means 3,600 men supported constantly who are doing no work.

Non-compensable cases reported are 14,833 per year with an average time loss of 4½ days or a total loss of 66,749 man-days, or 267 men supported constantly from this cause who are doing no work. The medical

fees alone for these non-compensable cases amount to \$9 per case, or a total of \$133,000 per year. Summarized briefly, one out of every five men in the industry is disabled through accident for some time during the year, and each accident is a potential fatality.

When a man is injured at a mine the work, invariably stops. If the man is killed, work usually stops for the day, and oftentimes for the day of the funeral. In any and every case hoisting and output is delayed until the injured man is out of the mine. Every company or contract man underground stops to discuss the affair with his neighbor, and the morale of the mine is broken for that day. Not less than one three-hundred and sixty-fifth part of the total yearly overhead of the mine must therefore be charged to any accident that interrupts production for a day, or with a proportionate amount for interference with production for part of a day. This is a minimum estimate because it is often several days before the direct thought of the accident has worn off and the fellow workers are back to their usual efficiency.

EFFECT OF MINE ACCIDENTS IS GENERAL

Every accident means breaking a new man into the job. Our efficiency friends have estimated variously this direct cost to the industry. It depends, of course, on the importance of the job. For example, if the man injured is a motorman, it is several days before trips are coming out of his section of the mine with the speed and regularity attained by him before injury. Oft times, the new man derails cars or burns out motors, and is directly responsible for additional accidents. Thus the chain of interference may reach to every part of the mine. Even in cases of accident to the contract miner, the effect underground is more general than first thought would indicate.

The indirect effects of accidents are important. They cause discontent among the men and strain the relations between them and the company officials. These are a real though intangible part of the cost. The high accident rate at mines is an important factor in causing employees to demand a high wage rate.

We believe that the indirect costs of any accident to the mining company are at least equal to the direct cost of compensation insurance itself, making the total cost of an accident at least twice the compensation insurance rate. Roughly then, between 4 and 5 per cent. of the costs of running a mine are due to injuries and fatalities.

Surely, with accidents in English coal mines, that have greater natural hazards than we ordinarily find in this country, only about one-third as frequent as in American coal mines, there is opportunity for constructive prevention work and education in this country. The details to be applied to an average mine are yet to be devised. A saving of 2c. of operating costs per dollar on accidents is as real an engineering feat and as necessary as the saving of a like amount through proper haulage, hoisting or other ordinary conditions demanding engineering skill.

Up to the present time in this country, accident prevention at most mines has been a matter for the attention of officials too burdened with operating details to take the time and study necessary to build up a technique of accident-prevention work. No prescription can be made for the average mine in the matter of mine accidents until the accident experience for large groups of similar mines has been tabulated and diagnosed.

Investigation Determines Best Furnace for the Burning of Small Sizes of Anthracite*

Tests Made on Furnace Fired by Chain-Grate Stokers—Ignition Improved by Increasing Incandescent Surface of Brickwork—High Boiler Settings Provide More Time for Completion of Combustion

By A. R. MUMFORD†
New York City

TO ASCERTAIN how different features of furnace design influence the combustion efficiency of small size anthracite, a series of tests was recently conducted by our company on a four-drum water-tube boiler, twenty-nine and thirty tubes wide and sixteen tubes high, having 10,000 sq.ft. of heating surface, and fired by two chain-grate stokers. In this boiler the gases cross the tubes three times and are deflected by baffles of the usual type.

A section through the center line of one of the stokers is shown as a background in all figures. Beneath the grate are four separate air chambers to which air is supplied through three wind boxes from a main air duct. For our purposes we will consider the grates divided into four sections, one over each air chamber. Each wind box is equipped with slide dampers to control the air pressure under the section of the grate above the corresponding air chamber.

The fourth chamber is divided by two vertical partitions into three compartments, each controlled by a damper, so that if a hole appears in the fuel bed, the damper to the lateral compartment under the hole can be closed to prevent too much air from entering the furnace.

Two Coxe chain-grate stokers under each boiler are placed side by side and operated by means of separate controls. A center wall separates the stokers and extends to within two-thirds of the distance from the front of the furnace to the bridge wall. This center wall is racked back from the bottom, near the bridge wall, to a curtain wall at the front. The curtain wall extends from the top of the front arch to the bottom of the front water leg.

IDEAL STOKER BURNS ALL COMBUSTIBLE MATTER

The front arch is a sprung arch 10 ft. long, extending from the ignition arch to about 8 ft. from the bridge wall. The bridge wall rises vertically from the floor level to the boiler tubes and is joined to the first baffle. Coal is fed to each stoker through separate chutes, and the initial thickness of the fuel bed is controlled by the ordinary coal gates.

The function of the stoker is to carry coal into the furnace, remove the refuse from the furnace, and supply air to the fuel. By adjusting the pressures in the separate air chambers, air is furnished to the fuel in the required quantity so that, with the ideal stoker, all of the combustible matter in the fuel is gasified and only the incombustible matter passes over the end of the stoker to the ashpit.

The function of the furnace is to raise the temperature of the green coal entering on the grate to the igni-

tion point and to mix the gases, rich in combustible, from one section of the stoker with oxygen from another section so that the gases may be burnt completely before they reach the boiler. If a furnace does not afford means for completely burning the gases with a reasonable quantity of air before they reach the boiler, its design is imperfect. The quantity of combustible gas and excess air present in the gases as they reach the boiler shows how well the furnace performs the mixing function; and the ability to maintain ignition at different ratings shows how well the furnace ignites the gases.

LOSSES APPARENT WITH ORDINARY OPERATION

Observation of the ordinary operation of the boiler, furnaces, and stokers in the plant on which the studies were made indicated that losses existed because of the large quantity of combustible in the ash, because of high flue-gas temperature, and because of the presence of carbon monoxide in the flue gases. The loss due to combustible in the ash was high, partly because it was necessary to carry long fires to attain the required steam output and partly because particles of solid combustible were blown from the front of the grate and carried in suspension by the gases until the end of the stoker was reached, when the particles settled out of the gases and fell to the ashpit.

The high flue-gas temperature was due to the combustion of carbon monoxide in the boiler. It is evident that any combustion which occurs after the gases have reached the boiler will result in a higher flue-gas temperature, because the further away from the furnace that combustion takes place, the less the boiler heating

Fig. 1—Normal Operation with Low Arch

Immediately over the fuel bed at the front of the furnace there is little or no oxygen but much combustible gas. The fuel is being divested of its water vapor, and is ignited only near the surface. Consequently the air is not in contact with incandescent carbon long enough to use up all the oxygen.

†Fuel engineer, New York Steam Corporation.

Fig. 2—Effect of Increasing Air Pressure in Last Air Chamber

At the rear of the furnace the oxygen is much higher with the increased pressure. At the entrance to the front pass the effect of increased air supply is quite evident. The gas composition did not change materially at the front of the furnace.

surface available for the absorption of the heat thus generated. The loss due to carbon monoxide in the flue gases and that due to high flue temperatures evidently were caused by the imperfect mixing of the gases in the furnace. Thus, to improve the operation of the plant, it was necessary to decrease the loss due to solid combustible carried in suspension by the gases, to burn out the refuse on the grates more completely, and to mix air with the combustible gases so that they would be completely burned in the furnace and away from the boiler.

In order to learn how the mixing action of the furnace might be improved and to outline accurately the path of the gases through the furnace, simultaneous samples of the gases in the furnace were collected at eleven points. Six of these points were on a horizontal line about 6 in. above the fuel bed and five on a horizontal line just below the boiler tubes. The flue gases were sampled simultaneously by means of a special sampling tube which drew gas from the whole width of the uptake.

The temperature of the flue gases was measured by copper-constantan thermocouples inserted in the openings between the drums just below the uptake. In order to eliminate any error from momentary changes in the fuel bed, the gas samples were collected over a period of twenty minutes. During this interval the flue-gas temperatures and the air pressures under the stokers were noted every five minutes.

COMBUSTION UNDER NORMAL CONDITIONS

The results of some of the studies of the furnace gases are plotted on charts, Figs. 1 to 7, inclusive. The holes through which the sampling tubes were inserted into the furnace are indicated by small circles inclosing identifying numbers. The composition of the gases at each point is plotted on the vertical line immediately above each sampling hole. The pressure of air in each of the four air chambers is represented by a horizontal line drawn across each section. In some diagrams, for the purpose of ready comparison, two sets of analyses are reported on the same chart and a heavier line is used for one of the sets in order to distinguish between them. The background of each chart is an outline drawing of the furnace and stoker during the study shown.

Fig. 1 shows the composition of the furnace gases under normal operating conditions. A study of the curves in this figure shows that immediately over the

fuel bed at the front half of the furnace, little or no oxygen is present and much combustible gas. At the rear half of the furnace much oxygen is present and little or no combustible gas. In the first pass more oxygen is present near the curtain wall than near the bridge wall, and conversely no combustible gas is present near the curtain wall although a rather large quantity is present near the bridge wall. A study of these and other analyses enables us to trace the progress of combustion on the grates and in the furnace.

As the coal falls on the moving grate it is brought slowly forward and exposed to radiation from the furnace brickwork, and at nearly the same time it passes over the first air chamber in which the greatest air pressure is carried. The radiation evaporates the surface moisture in the coal, and the air forced through the fuel bed by the pressure in the first air chamber carries the water vapor into the furnace. After the coal is dried, its temperature is raised to the point of ignition by further radiation. Ignition occurs first of all at the upper surface of the fuel bed, and the air passing through the layer of coal unites with the ignited coal and combustion begins. The rise in temperature caused by this combustion at the surface is communicated to the lower layers of the coal by conduction, and these lower layers then ignite and burn. After the coal is completely ignited in this manner, combustion of the whole fuel bed continues until no combustible is left on the grates. From the point in the travel of the grate where ignition is complete to the point of dumping, the combustible content of the fuel bed decreases steadily and the proportion of incombustible matter increases correspondingly. The influence of these changes in the combustion of the fuel bed on the products of combustion is exceedingly important in the design of a furnace.

EVAPORATION OF MOISTURE AND ITS REMOVAL

The first change in the fuel bed is the evaporation and removal of the surface moisture, and as this change is not a chemical reaction it has no influence on the oxygen content of the air. The second change is the distillation of the volatile matter and the ignition and combustion of the surface layer of the fuel bed. At this point some free oxygen is present above the fuel bed and little or no combustible gas, because the layer of burning coal is so thin that the air is not in contact with incandescent carbon long enough to use up all the oxygen.

As the fuel bed becomes fully ignited the oxygen in the air passing through the fuel is completely used up in the lower layers where it gasifies carbon and forms carbon dioxide. As this dioxide passes through the upper layers of incandescent fuel some of it is reduced to carbon monoxide by contact with carbon. Fully one-third of the length of the grate is covered by the fuel undergoing this change, and consequently a large volume of combustible gas is formed. This action continues until the carbon or combustible content of the fuel bed is lowered sufficiently to allow carbon dioxide to pass through with little reduction of carbon monoxide.

The quantity of combustible on the grate diminishes rapidly from this point on, and more and more free oxygen passes through the fuel bed until no carbon dioxide or carbon monoxide is formed, and the gases rising from the grates consist solely of air. To summarize, free oxygen is present at the very front and at the rear, while in between a large quantity of com-

bustible gas is present. In order to burn the coal completely in the furnace these three streams of gas must be mixed.

EVIDENCE THAT GASES MIX ABOVE GRATES

The extent of the mixing action of the furnace on the stream of gas can be seen by the changes in composition of the gases which have taken place between the grate level and the point of entrance to the boiler. At points 7 and 8, Fig. 1, no carbon monoxide was ordinarily present under normal operating conditions. The burning out of carbon monoxide was probably due to the fact that the air from the front of the stoker passed along just under the main arch, mixing with the combustible gas and burning it. The presence of carbon monoxide at points 9, 10, and 11 indicates that insufficient air was introduced into the main stream of combustible gas.

The gaseous products of combustion evidently acquire considerable velocity as they pass under the front arch, because the gas stream could be seen to pass toward the rear of the furnace beyond the end of the main arch before turning to enter the boiler. The stream actually impinged on the bridge wall which with the stack draft changed its direction toward the heating surface of the boiler. The presence of the main gas stream nearer the bridge wall than the curtain wall is confirmed by the analyses of the gases entering the boiler and by pitot-tube measurements, which indicated that the velocity at points 9, 10, and 11 was four to six times that at points 7 and 8.

SPEEDING GRATE LETS IN MORE AIR AT FRONT

It was found that combustion at point 1 is more complete when the grate travels fast and this indicates that more air enters the furnace at the front. An increase in air entering at the front of the furnace can only take place through green coal, and if the thickness of the fuel bed and the pressure of air in the first air chamber are the same, then there must be a larger area of green coal exposed to the pressure in the first air chamber at higher grate speeds to account for the more complete combustion at point 1.

In other words, as the grate travels faster, ignition takes place later. To check these deductions, the air pressure in the first chamber was reduced while the grate was moved at maximum speed, and it was found that the gas composition at point 1 was then the same

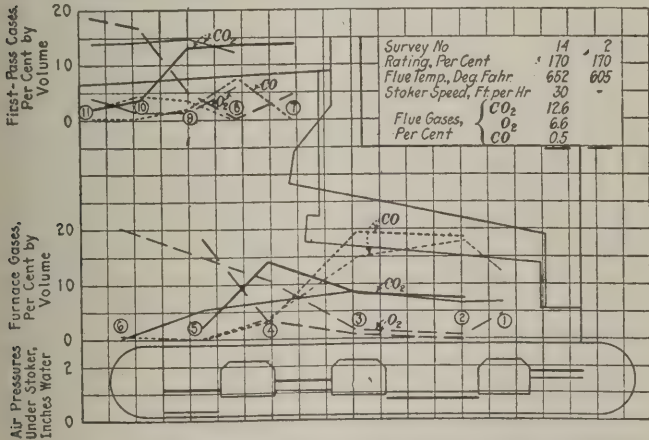

Fig. 3—Effect of Raising the Front Arch

This arrangement effected a reduction in the quantity of carbon dioxide and an increase in the quantity of oxygen showing the gas composition was not favorable to the high arch. There was little change in the quantity of combustible gas reaching the boiler.

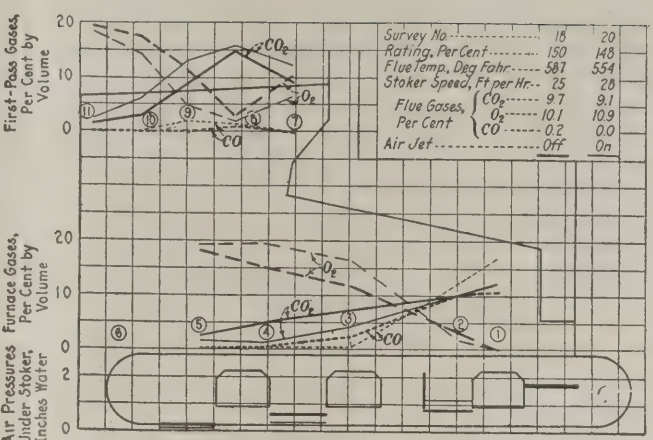

Fig. 4—Effect of Air Jet with Partition in No. 2 Air Chamber

The air jet reduced the quantity of carbon monoxide in the gases reaching the boiler, but it accomplished this with a large increase of excess air. The effect of an air jet in burning out carbon monoxide seems to be balanced by an increase in flue gas due to excess air, so that little real benefit is derived from the use of such a jet.

as at lower speeds. It was also found that the air from the front was responsible for the complete combustion of carbon monoxide by the time the gases reached points 7 and 8 for, with the reduced air pressure in the first air chamber, carbon monoxide was found at points 7 and 8. To circumvent the later ignition at higher grate speeds, radiation to the green coal must be increased by an increase in the area of radiating surface or by removing the obstruction caused by a thick ignition arch.

A study of the normal operating conditions indicates three possibilities for improvement. If the velocity of the gases as they pass under the front arch can be reduced materially, the number of particles of solid combustible carried to the rear of the stoker will be reduced. The obvious method of decreasing the gas velocity is to increase the cross-sectional area of the furnace under the front arch by building a higher arch. If this should improve combustion at the same time, because of the resulting increase in combustion space, it will be beneficial in solving two of the difficulties.

In order to burn out the combustible on the grates more completely, more air must be forced through the fuel bed on the last stoker section, with the single qualification that it must be possible to mix the additional air with the gases so as to complete the combustion in the furnace. In other words, it must be used so as to avoid losses due to excess air.

It might be advisable to introduce air into the furnace through jets under pressure in order to complete combustion in the furnace. All of these possibilities were tried and the results are shown in the following paragraphs.

INCREASED AIR AT REAR UNDESIRABLE

In order to study the effect of adding more air by increasing the pressure in the last air chamber, a set of samples was collected with no change other than the increase in pressure mentioned. The results are given in Fig. 2. The light lines indicate normal operation and the heavy lines indicate the effect of the additional air introduced through the refuse at the end of the stoker.

The results show that immediately above the fuel bed the gas composition did not change appreciably at the front of the furnace, but at the rear the oxygen is much

higher with the higher pressure. At the entrance to the first pass the effect of the increased air supply is very evident. The gas composition at points 7 and 8 is essentially the same for both trials. At point 9 there is evidence of a slight affect of the additional air, while at points 10 and 11 the rapid fall of the carbon-dioxide curve and the rise of the oxygen curve show that the additional air affected the gases passing these points materially. It is true that carbon monoxide was reduced, but the reduction in carbon dioxide and increase in oxygen showed the method to be impractical.

RAISING MAIN ARCH NOT RECOMMENDED

In an attempt to reduce the loss from particles of solid combustible blown from the front of the grate and carried to the ashpit, the main arch was raised to the level shown in the background in Fig. 3. The arch was raised 1 ft. at the front and 2 ft. at the rear, thus

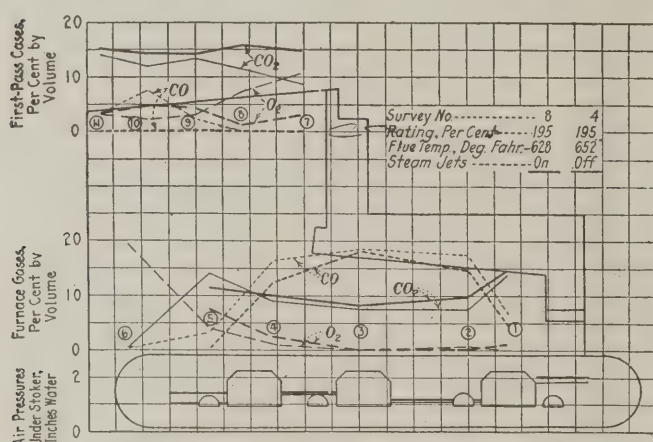

Fig. 5—Effect of Steam Jets with Low Front Arch

The air rising through the refuse is forced forward by action of the steam jets and mixed with the main gas stream. Thus the oxygen in this air is brought in contact with the combustible gas and combined with it burning the carbon monoxide and increasing the carbon dioxide. In the first pass the former is entirely eliminated.

increasing the cross-sectional area at the rear by about 16 sq.ft. and by about 8 sq.ft. at the front. This is somewhat greater than a 50 per cent increase at the end nearest the bridge wall, and ought to reduce the mean horizontal velocity by the same proportion.

The composition of the gases over the fuel bed and entering the boiler are shown by the heavy lines in Fig. 3. In this figure the background shows the two heights of arches. The light lines show the composition of the gases with the low arch, and the heavy lines indicate the gas composition with the high arch.

If raising the front arch is to improve combustion, the percentage of carbon dioxide found in the gases entering the boiler must be higher and that of carbon monoxide lower than with a low arch. It was impossible to determine exactly what weight to give the analyses at the various points, but if we assume that the points apparently in the main gas stream should be weighted according to the rough measurements of velocity that were made, points 9, 10, and 11 would have a weight of four to a weight of one for points 7 and 8, with the low arch in service. With the high arch, points 7, 8, and 9 would have a weight of four and points 10 and 11 a weight of one. Using the foregoing approximation the average composition of the gases entering the boiler shown in Fig. 3 is as follows:

	CO ₂	O ₂	CO	N ₂
With low arch, per cent.....	13.8	2.9	2.9	80.4
With high arch, per cent.....	12.1	5.4	2.8	79.7

From this it is evident that there was little change in the quantity of combustible gas reaching the boiler, but that there was a reduction in the quantity of carbon dioxide and an increase of oxygen so that the gas composition was not favorable to the high arch.

It is evident that if more air were forced through the refuse it would rise directly to the boiler past points 10 and 11 without coming into contact with the main stream of gas at all. With the low arch such an increase in air supply raised the excess of air, but with a high arch the effect would probably be worse in that none of the combustible gas would be eliminated by the accompanying increase of excess air.

The changes in the composition of the gases over the fuel bed were evidently not due to the change in arches.

In general as the raising of the front arch did not reduce the horizontal velocity of the gases sufficiently to stop the loss due to particles of solid combustible dropped from the gases to the ashpit, and as the composition of the gases entering the boiler was not improved, this change was not the most desirable.

No. 2 air chamber is that space under the grates between the first and second wind boxes. The distance between the sides of these two wind boxes, in the direction of the movement of the grate, is nearly twice the distance between wind boxes 2 and 3.

A partition was installed in each of the stokers of the boiler on which the investigations were made and is indicated by the vertical line in No. 2 section on the background of Fig. 4. The composition of the furnace gases at the several points is shown by the light lines in this figure, and, at low rating, the shortness of the fire is clearly shown. Because the carbon monoxide formed at the front of the fire had to pass under the front arch for a considerable distance before rising to the boiler and because oxygen was present in the gases below the arch, due to the short fire, there was somewhat less carbon monoxide in the gases entering the boiler. At the same time the greater quantity of oxygen passing through the fuel bed raised the excess air in the flue gases somewhat as shown by a comparison of the flue-gas composition for survey 14 (Fig. 3) and survey 18 (Fig. 4) at nearly the same rating.

AIR JET NEAR FRONT ARCH SHOULD BE OMITTED

The heavy lines in Fig. 4 show the effect of an air jet on combustion. The air jet was introduced through the side wall of the furnace about a foot below the end of the front arch and was supplied with air from a railway-type compressor which gave a pressure of about 25 lb. at the nozzle of the jet which was formed from a piece of ½-in. pipe. The differences in the composition of the gases over the fuel bed were caused by slight differences in the lengths of the fire.

As shown in Fig. 4, the oxygen at points 7 to 11, inclusive, was higher with the air jet in service and the carbon dioxide and carbon monoxide were lower. Thus the air jet reduced the quantity of carbon monoxide in the gases entering the boiler, but it accomplished this with a substantial increase in excess air.

At high ratings also, a reduction in the quantity of carbon monoxide in the gases entering the boiler took place accompanied, as at low ratings, with a decrease in carbon dioxide and an increase in oxygen when the air jet was in service.

The effect of an air jet in burning out carbon monoxide seems to be balanced by an increase in flue-gas loss due to excess air, so that little real benefit is

derived from the use of such a jet. In addition, it is illogical to provide an air supply above the fire if air can be forced through the refuse and properly mixed with the combustible gases. That the logical place for the admission of any air necessary for combustion is through the refuse is evident from the fact that air entering the furnace in such a manner must gasify some carbon and so reduce the loss due to combustible in the refuse.

STEAM JETS USED TO SIMULATE REAR ARCH

In order to simulate the action of a rear arch without waiting for its construction, a system of steam jets was introduced across the stoker at point 6 at the rear of the furnace. The steam jets were constructed by inserting sixteen 1/2-in. pipe nipples into a 1-in. pipe 8 ft. 8 in. long, and it was assumed that they would give an indication of the probable effect of directing the air rising through the refuse toward the front of the furnace where the necessity for such air has been shown.

The effect of the steam jets with the low arch in service is shown in Fig. 5. In this figure the light lines indicate the gas composition under normal operation and the heavy lines the composition with the steam jets in service. The combustion of the coal on the grates is, of course, unaffected by the steam jets. In the first pass, however, the effect of the additional air and the mixing action of the jet is evident.

The air rising through the refuse is forced forward by the action of the steam jets and mixed with the main gas stream. The oxygen in this air is thus brought into contact with the combustible gas and combined with it, burning the carbon monoxide and increasing the carbon dioxide. The composition of the gases in the first pass shows that by the time the gases have reached the boiler tubes the carbon monoxide is entirely eliminated. The following table gives a comparison of the two sets of analyses of the gases entering the boiler by means of averages weighted as formerly.

	CO ₂	O ₂	CO	N ₂
With steam jets, per cent.	14.8	4.0	0.1	81.1
Without steam jets, per cent.	12.7	3.7	3.7	79.9

From these results it is evident that steam jets gave the greatest improvement of any change discussed thus far.

BEST CONDITION FOR USE OF REAR ARCH

Because some of the arches in the boilers at the plant had been raised, it was desirable to learn the relative effect of steam jets on the combustion in a high-arch boiler. The curves in Fig. 6 show the results of an investigation on a high-arch boiler with and without steam jets. The heavy lines indicate the composition with the steam jets in service and the light lines the composition under normal operating conditions. The following tabulation gives a comparison of the weighted averages of the gas composition.

	CO ₂	O ₂	CO	N ₂
With steam jets, per cent.	12.4	6.6	0.5	80.5
Without steam jets, per cent.	13.0	4.5	2.2	80.3

It is evident, therefore, that steam jets—used to simulate a rear arch—were effective with a high arch but not as effective as with a low arch. This fact is of importance in deciding the best arch arrangement over a chain-grate stoker burning small sizes of anthracite.

To confirm the conclusions drawn from the action of steam jets a Detrick flat-suspended arch was installed in the rear of a low-arch furnace. The rear arch was

suspended 10 in. above the grate and extended 5 ft. forward from the bridge wall. The boiler was operated for several days at ratings varying between 250 and 270 per cent in order to learn the ability of the arch to withstand the heat of the furnace before a study of the furnace gases was undertaken.

During this period the dropping of particles of solid combustible matter from the gases to the ashpit stopped completely; this material dropped to the roof of the suspended arch instead and seemed to burn out, leaving a layer of ash which increased in thickness until it flowed slowly toward the grates, forming “whiskers” on the nose of the arch. The nose itself was brilliantly incandescent, although a layer of clear gas from the last stoker section seemed to cling to its surface. In rising to the boiler there seemed to be an expansion of the

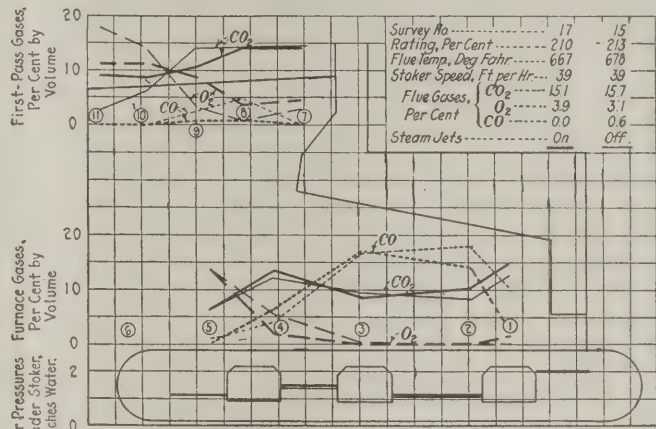

Fig. 6—Effect of Steam Jets with Raised Front Arch

The steam jets gave improved results. More carbon monoxide was burned to carbon dioxide. However, it is clear that the steam jets were not so effective with a high front arch as they were with one which was low. The weighted average of carbon monoxide was decreased only 1.7 per cent as against 3.6 per cent with a low front arch.

gas stream so that the whole width of the first pass was taken up by the gases entering the boiler.

The shape of the arch and its relation to the furnace is shown in Fig. 7. In this figure the results of a study of the furnace gases with the rear arch—heavy lines—are superimposed on those of a study of the furnace gases without the rear arch installed—light lines. Over the fuel bed the gas composition is different, although this is obviously not due wholly to the rear arch. The air pressure in No. 4 air chamber was maintained considerably higher with the rear arch in service and the refuse passing over the end of the stoker appeared well burnt out.

In the first pass the gas composition shows that the carbon dioxide is higher at all points and that the carbon monoxide is lower. The arithmetical averages of the gas composition show that without the rear arch about one-fifth of the carbon monoxide formed in the furnace entered the boiler and that with the rear arch in service only one-twentieth. These facts indicate that the rear arch as installed greatly improved the mixing action of the furnace.

The analysis of the flue gases shows a very favorable condition. The flue temperature shows a reduction of about 35 deg. F., which in itself is the equivalent of 1 per cent saving. The saving resulting from the favorable gas composition and apparent condition of the refuse cannot be estimated because no reliable figures are available for comparison. However, the plant records will eventually bring out the actual saving and

as the saving obtained by the operators is the true saving, this will be the criterion on which this form of furnace design will be judged.

The first function of a chain-grate-stoker furnace is to ignite the coal. Ignition is by radiation from incandescent brickwork to the green coal as it enters on the grate. Ignition can be improved mainly by increasing the area of incandescent surface and by decreasing the thickness of the ignition arch so that less coal will be in its shadow, or by both of these changes. It has already been pointed out that the nose of the rear arch became incandescent at high ratings and was hot at low ratings, and as this part of the arch faces toward the front of the furnace, radiation from it must be received by the green coal. Because the bridge wall never was heated above a dull red heat, the radiation from it to the green coal must have been less than from the nose of the rear arch, and therefore ignition was hastened by the addition of this form of arch.

The other function of the furnace is to mix the products of combustion so that the combustible gases from one part of the grate will be supplied with oxygen from another part and burned before they enter the boiler. The investigations reported here were made on a furnace of the Dutch-oven type and the indications are that some such type is necessary to produce mixing. Air and combustible gases are present at the front of the stoker and some arch over this section is necessary to force the two streams into contact.

Because the air entering the furnace at the front is generally insufficient to supply all the necessary oxygen, the combustible gases from the front must be forced to pass over the refuse section of the grate in order to come in contact with the free oxygen in the gases rising from this section. This action can be accomplished by placing the stoker completely under an arch and thus preventing any of the gas from entering the boiler until it has passed over the refuse section. This form of furnace would have obvious disadvantages from the standpoint of upkeep because intense gaseous combustion would probably take place over the refuse section and the arch would be subjected to the resulting high temperature at this point.

It is well, therefore, to shorten the main arch from this extreme length to a length that will permit the radiation to the boiler to cool the brickwork at the point where the most intense combustion will take place. If the front arch is shortened in this manner it will be

necessary to install a rear arch to prevent the gases from the refuse section from rising directly to the boiler and to force them to travel toward the front of the furnace far enough to insure their mixing with the main stream containing combustible gas.

The front arch should be low enough to insure the gases having such a velocity as will enable their momentum to carry them beyond the end of the front arch and over the rear arch to the bridge wall. Combustion under the front arch can be made more incomplete than normally, if advisable, by a decrease in the air supply at the front; and the necessary oxygen for the completion of combustion can be supplied by carrying high air pressures under the refuse section of the grates.

The details of the dimensions of such a furnace would vary with the height of the setting available, because the higher the setting the more time there will be available for the completion of combustion. Conversely, the lower a setting is the more effective must be the action of the mixing devices in order that combustion be completed before the gases reach the boiler. However, it seems necessary to utilize arches in the manner suggested, because by that means the gas streams from the front and rear of the stoker will give velocities in opposite directions such as will insure complete combustion of the gases within the furnace.

Bureau Seeks Way to Reduce Screenings

Coal mine operators in Illinois have requested the Department of the Interior to authorize the Central District Experiment Station of the Bureau of Mines, at Urbana, Ill., to conduct a study of the problem of reducing the proportion of screenings in the coal mined in that state. This is said to have become a quite acute problem with Illinois coal operators.

The market for Illinois coal is largely one for coal to be used in heating dwelling houses. The demand, therefore, is for the larger sizes. So acute is the situation that often there are hundreds of unbilled cars of screenings, but not one of lump. This problem of screens has been growing more intense since the plan of paying the miners for "run-of-mine" tonnage rather than for "screen coal" tonnage came into existence. While there are other factors involved one of the most important causes of this excess of screenings, according to the Bureau of Mines, is the method employed in the use of explosives.

Alaska Coal Field Making Haste Slowly

Plans for close co-operation between officials of the Alaskan Ry. and the U. S. Bureau of Mines, in all matters pertaining to mining along the railway belt have been developed. The arrangement is designed especially to facilitate the mine-rescue and first-aid service of the bureau. A distinct improvement in safety conditions in the coal mines of Alaska, particularly in the use of proper explosives and in providing adequate ventilation, is evident.

In the Matanuska coal field, the Evan Jones washery, put in operation in November, is delivering a satisfactory washed coal, for steam and domestic use in the towns of Juneau and Ketchikan. The ash content is reduced from 22 per cent to 14 per cent by washing, with an increase in heating value. After a prolonged shutdown, the Suntrana coal mine, in the Nenana field, is again operating.

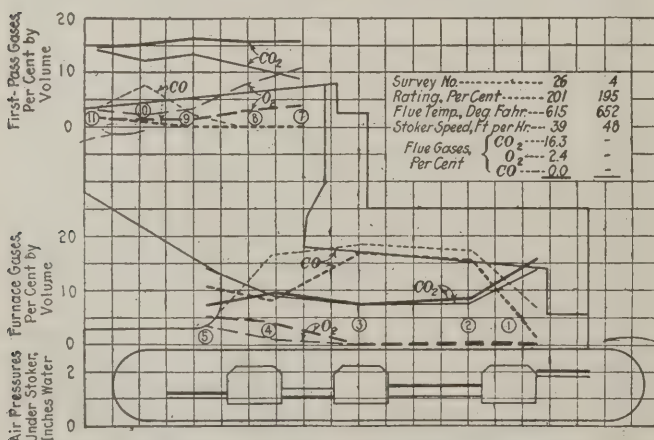

Fig. 7—Actual Effect of a Rear Arch

Analyses over the whole fuel bed showed marked improvements. The flue temperature showed a reduction of about 35 deg. F. The dropping of particles of solid combustible matter from the gases to the ashpit also stopped completely.

News Of the Industry

Mine Blast at Castlegate, Utah, Takes Heavy Toll of Lives

Hope of Finding Any of 173 Entombed Miners Alive Is Remote—Company Officials Reluctant to Assign Cause for Explosion—One of Rescuers Succumbs—All Fires Extinguished

Special Dispatch to Coal Age

A series of explosions in Mine No. 2, of the Utah Fuel Co., at Castlegate, Utah, at about 8:40 a.m., March 8, entombed 173 miners. Three successive blasts wrecked the mine portal shortly after 116 men had entered for the morning shifts. There were also 57 night men within the workings when the disaster occurred. The bodies of 58 victims had been recovered when this issue went to press, and hope of finding any of the others alive had almost been abandoned.

The force of the explosion blew out the bulkhead of the old entrance to the property and scattered debris covered the mountainside across the canyon with soot and slag for several hundred yards. For several hours following the explosion the gases and smoke so filled the canyon that it was stifling.

U. S. Bureau of Mines rescue cars were rushed to the scene, one from Dawson, N. M., and the other from Butte, Mont.

Early reports of havoc wrought by fire proved incorrect. It is declared that all fires have been extinguished. Work of the rescue teams have been speeded up, but is still slow owing to the distance bodies have to be carried. The mine evidently was literally riddled by the explosion and it is feared that those whom the blast did not kill were poisoned by the gases.

There is no way of determining where the first blast occurred because of the obstruction near the entrance. There are both 12 and 18 ft. entries to the bottom of the mine. About 40 per cent of the workers were in the dip end more than 7,000 ft. from the main portion and more than one mile from the entryway opening, which are the only two means of egress from the workings.

The company has four camps in all with 10 or 12 openings. It is impossible to say anything at present regarding the probable property damage. The fan has been started again. The explosions were so great that the debris thrown into the passage to the mine entrance was considerable, making the work of rescue exceedingly difficult. It is feared some days may elapse before the men or their dead bodies may be reached.

There were three or four explosions. The first was not sharp, it is stated. According to the townspeople it sounded like the tremble of thunder reverberating across the hills. Telephone and electric light poles, timber and pipes near the manway were blown across the valley, almost a mile in width, so tremendous was the force of the explosion. As further evidence of the impact, poles were splintered into kindling and boulders and pipes were scattered everywhere. The second explosion, one minute later blew the wall out of the fanhouse. The third explosion followed 20 minutes later, causing a cave-in. The office building of the company, 100 ft. away, was partly wrecked.

Offers of relief are coming in from state and national organizations and Governor Mabey has decided to issue a nationwide appeal for funds to be used for relief of the widows and dependents. Estimated dependents number 868 women and children. In addition to the relief fund it is estimated that each family will have \$5,000 from the workmen's compensation law.

Bureau of Mines officials have expressed the opinion that 72 hours is the minimum time it will take to remove the bodies from the mine. One of the victims is John Thorpe, general inspector for the company, who leaves a widow and five children.

Company officials are reluctant to express an opinion regarding the cause of the explosions. General Mine Superintendent Littlejohn said the mine was inspected and sprinkled as usual on Saturday morning and that at that time there was no indication of danger. So far the cause of the explosions appears to be a complete mystery. The mine was considered to be in first class condition by every one. The inquest is not expected to bring many facts to light as to the cause of the explosions, owing to the fact that hope of rescuing any of the victims alive is vanishing hourly.

No one, so far, seems to suspect any unlawful act on the part of an employee or other person. The men had been on short time, but a feeling of good will appeared to prevail and there is said to have been no agitation of any kind.

Castlegate Mine No. 2 of the Utah Fuel Co. has been the largest producer of that company for a long time. It was opened in 1912 and has been producing in excess of 1,500 tons a day. It was good for from 30 to 50 years more, it was stated at the chief offices of the company.

It is nearly 25 years since Utah had a mine disaster on anything like a scale such as that which befell her on March 8. On this occasion 200 men were suffocated by afterdamp. The tragedy occurred at Winterquarters, where the property also belonged to the Utah Fuel Co.

U. S. Supreme Court Upholds Kansas Industrial Court

In an opinion delivered March 11 the U. S. Supreme Court held in the case of August Dorchy that the provision of the Kansas Industrial Relations Court Act which prohibits strikes by coal miners must stand or fall on the decision of the Kansas courts. The decision of the lower federal court in issuing a writ of mandamus was reversed.

Justice Brandeis, delivering the opinion, said the Supreme Court could, if it desired, pass upon the validity of the section in question, but that it would rather leave that point to the state courts, and would accept their decision. He declared that the lower courts should not have passed upon the question.

Dorothy and Alexander Howat, district officials of the United Mine Workers, were indicted for calling a strike at the mine of the George K. Mackie Fuel Co. in Cherokee County, Kansas, and were convicted under the Kansas Industrial Relations Court Act, which designates coal mining as an essential industry affected with a public interest. They contended that a state could not arbitrarily make such a classification.

The state courts have held that application of the act to the mining industry was valid.

Central Pennsylvania Miners Convened at Altoona

Altoona, Pa., March 11.—The convention of United Mine Workers of District 2 (central Pennsylvania) was called to order at 10 a.m. today with President John Brophy in the chair. Mayor E. F. Gills made an address of welcome to the four hundred delegates present, after which President Brophy submitted a report reviewing his work during the last year. The convention probably will last all week and the miners' representatives will meet with the operators March 20.

Northern West Virginia Balks at Jacksonville Pact

A number of operators in northern West Virginia are outspoken in opposition to the Jacksonville agreement. As one operator expressed it, "the future of union mining in the county depends largely upon the attitude of the miners between now and March 31. Many operators contend that it is a foregone conclusion that the northern West Virginia field cannot accept the Jacksonville agreement and continue to operate. We will have to have a substantial readjustment of the scale or all of the union mines in the district will be shut down after March 31." There is already a considerable tonnage coming from mines operated on a non-union basis along the Monongahela R.R. and in other sections of northern West Virginia and the ranks of the non-union mines may be further augmented owing to the fact that the union mines may not be able to compete with the non-union mines owing to the lower scale of wages in effect at the latter.

Negotiations have been initiated for a conference between officials of the Monongahela Coal Association and the Northern West Virginia Coal Operators' Association at which time preliminary steps will be taken looking to a joint conference of operators and miners, when the mine owners will ask for a concession in wages. Union representatives are not expected to make any concession inasmuch as they never have in district 17 deviated from the agreement made to cover the Central Competitive Field. Hence it seems probable that many northern West Virginia mines after March 31 will either be closed down or where mines are continued in operation it will be on a non-union basis and with a lower scale of wages prevailing.

To Hold National Parley on Uniform Cost Accounting

A national conference on the development of uniform cost accounting will be held at the Hotel Astor, New York City, on Tuesday and Wednesday, March 25 and 26, under the auspices of the Chamber of Commerce of the United States. Invitations are being sent to the representatives of the three hundred principal manufacturing industries of the country. It is expected that there will be a large attendance of association executives and others interested in cost-accounting activities.

On the morning of the first day executives from important industries getting good results from uniform cost accounting will tell about it and answer questions. The afternoon will be devoted to the exchange of experiences as to "The First Steps in Cost Accounting in a Trade Association—How to Arouse Interest."

The second day will be devoted to the more advanced problems, among which will be considered "The Service of the Cost Accounting Committee in Developing Uniform Methods." In the afternoon attention will be given to "How to Get the Uniform System Into Use by the Members of the Industry."

William Newton Logan

Dr. Logan, who is State Geologist of Indiana, has been made a fellow of the Royal Society of Arts, London, in recognition of his work in geological science.

Pittsburgh Coal Co. Has Big Year; Earns \$7,309,162

The Pittsburgh Coal Co. earned \$7,309,162.31 in 1923, after full charges for interest, depletion and depreciation, but subject to federal income tax, according to the annual report of the company, issued March 10. Gross receipts were \$63,069,472 and operating expenses were \$51,710,916. The available working capital of the company at the end of the year, exclusive of U. S. Government bonds and other securities owned, was \$18,528,767.23, a net increase during the year of \$339,043.56.

The company and its subsidiaries produced 13,915,588 tons of bituminous coal last year. Of this, 12,531,575 tons was from mines in the Pittsburgh district, 1,152,061 from mines in Ohio and 241,952 tons from its mine in eastern Kentucky. This is the largest output by the company since 1919, representing an increase of more than 100 per cent over 1922, when operations were suspended for five months by the strike.

The company had 64 mine plants at the beginning of the year and 11 additional mines were acquired with the Great Lakes Coal Mining Co., bringing the total to 75, of which 1 was sold and 2 were not in commission. Of the total in commission, 64 were operated all or part of the year, 5 were idle and 3 were leased. In the Pittsburgh district the mines in operation in the first half of the year numbered 46; in July and August, 45; in September and October, 44; in November, 36, and in December, 27.

Declare Claim Not Justified

Since 1916 the Myers-Whaley shoveling and loading machines have been made in a completely equipped plant devoted exclusively to their manufacture. Mr. William Whaley, the general manager, in a letter of March 4 draws attention to that fact in correction of a similar claim made by another company which appeared on page 327 of *Coal Age* of Feb. 28.

Treadway Scores Pinchot for Anthracite Settlement

Governor Pinchot of Pennsylvania is severely criticized for intervening in the anthracite strike in a letter to him made public in Washington, D. C., March 5 by Representative Treadway of Massachusetts. Referring to a brochure issued by Governor Pinchot, Representatives Treadway in his letter, says:

"You endeavor to justify the agreement you entered into on Aug. 27 last, whereby there was an increase of 10 per cent in wages of miners, and point out that this should not have led to any increase in cost to the consumer. As a matter of fact, you no doubt are well aware that it has resulted in an increase of 75c. to \$1 per ton to all consumers in New England. At the annual meeting of the United Mine Workers in Indianapolis a few weeks ago, Mr. Lewis, the president, stated that the wages of the miners had been increased by \$44,000,000 as a result of this adjustment, which laid a direct toll on the consuming public.

"It is surprising that you should defend the anthracite tax in your state. You say the repeal of this tax was before the Legislature of 1923, but failed to pass. Why do you not state the reason for its failure to pass, namely, your personal influence in opposition to it, even though your campaign committees published flaring advertisements of your support of repeal?

"Your argument of the small amount of this tax is a very weak one. In the aggregate it adds from \$8,000,000 to \$10,000,000 of expense to the coal-consuming public in order to care for, as it has been stated, deficiencies in the appropriations of your state."

Hero Medals to Four Miners, Including Jones, Who Died

Four coal miners whose acts stood out prominently in last year's mine disasters are to receive hero medals and diplomas on the recommendation of the Joseph A. Holmes Safety Association. One of the awards will be made posthumously. The medals and diplomas will be presented at the Seventh International First Aid and Mine-Rescue Contest at Huntington, W. Va., Sept. 11.

The miners and the deeds for which the awards are to be made follow:

Mike Pavlisin and Clifford Phillips of Frontier, Wyo., who, by "prompt and courageous action," saved the lives of twenty-one fellow miners after an explosion in the Frontier No. 1 Mine of the Kemmerer Coal Co., Kemmerer, Wyo., on Aug. 14, 1923, which resulted in the death of ninety-nine men.

Eben W. Jones, of Peckville, Pa., who saved six lives on the occasion of a roof collapse in the Mount Jessup Coal Co. (Ltd.), property at Peckville, Pa., on Dec. 8, and sacrificed his own life in attempting to rescue four others.

Isaac Cotton, of Jasonville, Ind., who rushed into a cloud of smoke caused by a powder explosion in the mine of the Merchants Heat & Light Co. at Jasonville, on April 18, and carried two men—their clothes aflame—to the surface. The two men, who were brothers, died from their injuries.

West Kentucky Upset by Consolidations And May Go Entirely Non-Union

Labor Policy Difficult to Determine While North American Co. Dickers
for Control of Hart, Kentucky Block and
St. Bernard Mining Properties

The western Kentucky coal field is in a perturbed condition. Nobody knows what the labor situation in the region is going to produce, and the pending consolidation of four of the main companies is leading to all sorts of speculation. It is now definitely known that the North American Co., owners and operators of public utilities throughout the Middle West, is negotiating not only for the St. Bernard Mining Co. but also for the properties of the Hart Coal Corporation and the Kentucky Block Coal Co. When all these are grouped with the non-union West Kentucky Coal Co. it is predicted that the whole western end of the state will scrap the union.

But the North American Co. has not yet bought all these properties. Engineering examinations and appraisals have been completed and the financiers interested in the proposal are negotiating without having reached a definite conclusion. An option on the St. Bernard properties running to April 26 is said to be bound by a forfeit of \$75,000 if the purchase is not made. This option is about to be exercised. If the North American Co. adds all three of the companies to its west Kentucky holdings it will control a potential output of about 500 cars of coal a day.

What is the relation of these negotiations to the western Kentucky labor problem? They have sufficiently excited the entire field so that no man knows what he can say to the union until the consolidation proceedings have culminated and the North American Co.'s labor policy is determined.

DISTRICT 19 MAY GO NON-UNION

There are two contracts with two sections of the west Kentucky field. An agreement between 5,000 miners of District 23 and operators of Christian, Hopkins and Webster Counties, excluding the St. Bernard Mining Co., has another year to run. The rest of the field has a contract with District 19 which expires March 31. Doubtless most of District 19 will now refuse to sign and will go non-union except in Muhlenberg County, where unionism is strong.

Of the coal properties about to be bought by the North American Co. the St. Bernard lies in that part of District 19 which no doubt will refuse to sign and will therefore go non-union. The Hart Coal Corporation, however, is in the three-county region of District 23, whose contract runs another year.

Of course the union would like to renew the three-county contract for three years and the other in 1925, for two years so as to run concurrently with the Central Competitive Field contract. There are many operators, however, who say they will never agree to a contract running longer than one year. Others are preparing to demand a return to the 1917 scale of wages and declare they will meet a strike

rather than grant anything higher. The politics of the situation is such, however, that a short-term contract may be made to avoid a tie-up.

The strippers of the field are an important labor factor, and may become even more vital. Already there are fifteen plants either working or ready to run, in most cases able to load out coal much cheaper than can the shaft operations. Well-designed cleaning and washing plants may be installed at more of them so as to give the coal an equal break on the market coal from shaft mines. Some of these mines are practically non-union since the only union men in the pits are the shovel operators, whose organization is in bad odor with the United Mine Workers of America.

This western Kentucky coal meets in various markets a great deal of eastern Kentucky output produced by miners working for varying wages averaging about the 1917 scale. What the producers will say to the miners in conferences to follow the March 11 meeting of the union miners in Louisville remains to be heard. Last week the sentiment was by no means crystallized and there were evidences of difficulty in getting such crystallization.

First-Aid Meet to Be Held at Huntington Sept. 11-13

The Seventh International First-Aid and Mine-Rescue Contest will be held in Huntington, W. Va., Sept. 11, 12 and 13, under the auspices of the Bureau of Mines, with the co-operation of the American National Red Cross, the National Safety Council, and various mine operators' associations and miners' organizations. It is expected that as many as 80 teams of miners trained in the first-aid and mine-rescue courses of the Bureau of Mines, will compete.

\$10,000,000 Stock Issue by Consolidation Coal Co.

Directors of the Consolidation Coal Co. have approved an issue of \$10,000,000 7 per cent cumulative preferred stock. Holders of common stock as of March 8 will be entitled to subscribe at par at the rate of one share of new preferred for four shares of common held. The proposal will be submitted for ratification at a special stockholders' meeting March 19. Proceeds from the sale of the issue will be used to pay the balance of the purchase price of the Sandy Valley & Elk Horn R.R. and to reimburse the treasury for other capital expenditures.

Cincinnati Convention Plans Set in Motion

Cincinnati, Ohio, will be the center of the coal-mining industry during the week of May 12 to 17 when the National Coal Association and the American Mining Congress hold their joint meeting. At a meeting of the Cincinnati Coal Exchange, Colonel E. O. Dana was appointed president of a committee to arrange for the annual convention of the National Coal Association. James Layne, Jr., will be the secretary, and W. T. Slaughter the treasurer. The meeting was held in the office of Stewart McVeigh, vice-president of the Island Creek Coal Co., after word was received from W. E. E. Koepler, chairman of the Convention Committee of the National Coal Association, that the invitation to meet in Cincinnati had been accepted.

The Manufacturers Division of the American Mining Congress has arranged to stage an exposition of coal-mining equipment and machinery and to work out a program covering informal discussion of the practical everyday equipment problems with which coal-mining engineers and operating officials are constantly confronted. The machinery exposition will embrace exhibits of the very latest types of mechanical equipment from approximately 125 representative manufacturing concerns. The display will be held in the North hall of the Cincinnati Music Hall, which is conveniently located and which will make an effective setting for the exposition. The sessions of the National Coal Association will be held during the mornings, leaving the entire afternoons free for an inspection of the displays and for the open-forum discussions of practical equipment problems, which will be worked out under the auspices of the Standardization Division and the Manufacturers Division of the American Mining Congress.

The headquarters of the National Coal Association will be at the Hotel Sinton and the headquarters of the Manufacturers Division and Standardization Division of the American Mining Congress will be at the Hotel Gibson.

Further information can be obtained from the American Mining Congress, Washington, D. C.

Canadian Miners Want More Pay

The agreement between the coal miners and operators in District 18, United Mine Workers, covering the southern Alberta and eastern British Columbia fields, expires on March 31, and the miners now are considering demands that are to be made for future operation. While nothing official has been announced, it is pretty certain that the miners' demands will include an increased wage and an agreement for a term of not less than three years. It also is quite certain that the operators will resist both demands. At the present time orders are slack, owing to the extended use of fuel oil on the railways and an unusually mild winter. Recently, the Crows Nest Pass Coal Co. closed two of its mines on account of no market.

Anthracite Safer and More Economical Than Oil

Anthracite is superior to oil for fuel purposes from the standpoint of safety, economy, practicability and desirability, according to a brochure issued by the Anthracite Bureau of Information, Philadelphia. The booklet is a reprint of an address by E. W. Parker before the Philadelphia Builders' Association.

Disastrous fires caused by oil-heating equipment in various parts of the country are cited as indications of the danger in its use. Issuance of a flood of summonses to court by the New York Fire Department for failure to obtain required permits as well as the refusal of the Fire Prevention Bureau to grant applications for dwellings with such installations also are cases in point. "It is different with anthracite. No rules are issued, no permits are required for the installation of an anthracite-burning equipment. It is absolutely safe."

In the matter of economy the booklet says: "The price of fuel oil in Philadelphia delivered in 500-gallon tank lots is 8c. a gallon, at which the cost of 153 gallons, the quantity required to produce the same amount of heat as a ton of buckwheat anthracite, would be \$12.24. The price of buckwheat delivered is \$8, the difference being \$4.24, or a little more than 50 per cent."

The use of oil fuel causes such speedy deterioration of boiler tubes and fittings that a Rhode Island plant was obliged to replace 1,500 boiler tubes in one year after oil-burning equipment had been installed. Anthracite, on the other hand, being low in sulphur, causes a minimum of injury to metal surfaces, insuring longer life to boiler tubes.

For domestic heating, says Mr. Parker, anthracite combines safety, economy, practicability and desirability, a number of simple and inexpensive devices now on the market making low-priced buckwheat available for that purpose, so that householders and building owners should think twice before changing their heating systems by substituting oil for anthracite.

New River Output Jumps on Resumption of 1917 Scale

Plants of the New River Co., operating in the New River district of West Virginia, are now producing coal at the rate of approximately 7,500 tons a day, equivalent to 187,500 tons a month. Production reached the present figure during the latter part of January, soon after the mines resumed operation upon the request of the miners and on the basis of the 1917 wage scale. It will be recalled that the mines suspended production on Jan. 14 owing to the low price prevailing on coal at that time, which made it impossible to produce coal at a profit with the higher scale of wages in effect. It is stated that since the resumption of operation at the lower level of wages the company has been able to operate profitably. It was possible to readjust wages to meet market conditions owing to the fact that the mines of the company are operated on a non-union basis.

Dempsey Ducks Bout with Old Battle-Ax Coal

Jack Dempsey, champion heavyweight boxer of the world, has decided not to go into Utah coal with the Great Western Coal Mines Co. This appears in connection with the announcement that unless the public leases parts of two coal tracts totaling 1,600 acres in Carbon County which have just been segregated by the Secretary of the Interior, the company will take the lease and develop the land. The proposed mining town, which was to have been called Dempsey, probably will be called Coaltown. The initial investment that must be made in the two tracts within three years is \$45,000. After three years the output of the property must attain 25,000 tons a year.

New Record Made in Output Of Briquets in 1923

A new high record was established in the production of fuel briquets in 1923. Reports to the Geological Survey show that the total output was 696,810 net tons, an increase over production in 1922 of 77,385 tons, or approximately 12 per cent. This increase may be largely attributed to improvement in demand for briquets in the Eastern States, which resulted in an increase of 48 per cent in the output of plants in that territory. Production increased slightly in the Pacific Coast States, but in the Central States, where the largest increase in 1922 occurred, there was a decrease of 5 per cent.

Fuel Briquets Produced in the United States in 1916-1923

Year	Net Tons	Value
1916.....	295,155	\$1,445,662
1917.....	406,856	2,233,888
1918.....	477,235	3,212,793
1919.....	295,734	2,301,054
1920.....	567,192	4,623,831
1921.....	398,949	3,632,301
1922.....	619,425	5,444,926
1923.....	696,810	5,898,698

Of the 14 plants that operated 5 used anthracite culm or fines, 2 semi-anthracite, 2 a mixture of anthracite fines or culm and bituminous slack, 1 semi-bituminous slack, 1 bituminous slack, 1 a mixture of bituminous slack and sub-bituminous coal, and 2 carbon residue from the manufacture of oil gas.

The total quantity of raw fuel used was 682,490 net tons, an increase of 11 per cent over the quantity used in 1922. Of the total, 49 per cent was anthracite and semi-anthracite, 33 per cent semi-bituminous and bituminous slack, and 18 per cent sub-bituminous coal and oil-gas residue.

Raw Fuels Used in Making Briquets in the United States, 1920-1923

Fuel	(Net Tons)	1920	1921	1922	1923
Anthracite culm and fine sizes and semi-anthracite.....		356,877	190,964	254,563	331,102
Semi-bituminous and bituminous slack and coke.....		a 125,506	121,925	235,542	a 225,508
Lignite, sub-bituminous coal, and oil-gas residue.....		89,656	b 85,352	b 123,339	b 125,880
		572,039	398,241	613,444	682,490

(a) Includes no coke. (b) Includes no brown lignite.

State Completes Its Case Against Keeney

With the testimony of three witnesses the State of West Virginia on March 4 completed its case against C. Frank Keeney, president of district 17, United Mine Workers, which was begun on Feb. 11. Keeney is charged with being an accessory to the murder of John Gore, a Logan County deputy sheriff, and of complicity in the Logan armed march of 1921. Just as soon as the last witness for the state had testified the defense entered a motion to strike out the evidence of the state, whereupon extended arguments on the motion ensued.

The state sought through the last witnesses introduced to prove certain circumstances as to a conference between Keeney and others at the home of Henry Nichols at Dry Branch on Cabin Creek in which union officials and Walter Allen, alleged leaders of the armed march, too part. According to the testimony of Nichols, his wife and his daughter, Christine Nichols, there were present at the conference, Allen, Keeney, Fred Mooney, district secretary, and Harold W. Houston, chief counsel for the union in the present trial. The witnesses were unable give the gist of the proceedings at the conference other than frequent mention of Logan and Mingo counties. They declared that the conference occurred just before the miners began to assemble on Lens Creek for the march. Nichols and his wife both testified to seeing Keeney at Marmet.

The last witness for the state was the Rev. J. E. Wilburn, who had been on the stand earlier in the trial. He was recalled in order that he might be asked about a letter purporting to be from him to William Blizzard. Wilburn identified the letter but declared that some changes had been made in it.

J. F. Hayes, of Milton, and Joe Huff, former members of the Dobra local of the United Mine Workers, were important witnesses for the state, testifying as to a payment alleged to have been made by District Secretary Fred Mooney to Earl Hager for the purpose of obtaining guns and ammunition.

It was testified by William Swanner that several weeks before the armed march began, Mooney, in the course of a talk to the Clothier local members, had told the miners to get guns and had said "If you haven't got the money, the local has; and if the local hasn't got enough, the district and the International will back you up."

As a matter of fact most of the witnesses used by the state in its case against Keeney have been former members of the union, many of them participants in the armed march, according to their own admission.

Legality of Trade Statistics a Vital Issue As Keen Competition Looms Ahead

Failing Judicial Pronouncement, Statement of Administration Policy
Would Be Important Help to Coal Industry—Opportunity Seen
in Offer of Full Data to Commerce Department

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

It is so important to the coal industry to have reliable statistics if disaster is to be avoided during the period of intensive competition which is certain to result from the three-year agreement entered into with the United Mine Workers that attention at this time seems to be focussed on the question of legality of trade statistics. Steps are being taken to obtain the enactment of legislation that will make clear the rights of industry to have the information necessary to the intelligent conduct of business. In view of the existing situation, all agree that comprehensive and accurate statistics are more important to the coal industry at this time than to any other activity.

It has been suggested that the Department of Justice should bring a test case against an association engaged in clear-cut statistical activities. The department is understood to be disinclined to take such action, although it is believed to concede that these statistics are in the public interest. It also has been suggested, as discussed in this correspondence last week, that a friendly suit be brought against one of the local associations by a consumer of coal who could contend that he is being injured by the statistical activities of the association.

It is agreed that a long time will be required to obtain legislation. Moreover, it is a situation which could not be met in a legislative way without arousing the politician who believes he can profit by baiting industry. All agree that a judicial determination of the uncertainty would be best. In case there should be any hesitancy about initiating steps to that end, however, the next best thing, it is agreed, is to obtain a pronouncement of policy from the administration.

The situation is similar to that which arose when Pittsburgh operators appealed to Secretary Hoover for a statement of policy as to their participation in a wage conference with the United Mine Workers. Mr. Hoover assured them that such action would not be in contravention of the anti-trust statutes. While it was reassuring to the operators to have such an expression from the Secretary of Commerce, they realize that he had no control over the Attorney General. They were fully assured, however, when Mr. Hoover obtained from the President a similar expression.

It is believed some way can be found to obtain from the administration a definite statement of policy in connection with trade statistics. The position of the Secretary of Commerce is generally known. His efforts to clear up the situation thus far have been futile, as is indicated by his correspondence

with the Attorney General. It now is suggested that one of the coal-trade associations might be able to obtain a pronouncement of administration policy were it to make a definite offer to the Department of Commerce to furnish it with its full statistical reports. The offer would be accompanied by a specific statement that it did not expect any guarantee of immunity from prosecution. It would be made plain that the issue is being raised to develop a method of making the information available so as to comply in the fullest degree with the law and with the hints which the courts have given that any information gathered must be made available to all concerned on equal terms.

The right would be conceded to the Department of Commerce to check against the original returns the accuracy of any reports furnished by individual companies. The association might promise to accept any suggestion from the department as to the time and method under which the information would reach its members. If such an offer were made along with a guarantee that the information is accurate and that it will be distributed in a way intended to prevent misuse of the information, it would seem that such an offer would have to be accepted or rejected. Sympathetic as is Mr. Hoover, it is not improbable that he would be willing to carry the specific offer to the next Cabinet meeting and try to get an expression of administration policy.

It is difficult to see how the administration could decline to accept such an offer. At any rate it certainly would put the trade association making it in a most favorable light. It also is possible that the discussion of such an offer by the Cabinet might result in the initiation of a test suit by the Department of Justice, which is the step most desired.

Central Pennsylvania Wage Parley March 20

March 20 has been selected as the date for the joint meeting of the operators of central Pennsylvania and the officials of District 2, United Mine Workers. The meeting will be held in Altoona and it is expected that an agreement will be reached as a basis on which a wage scale to take the place of the present scale, which expires March 31, may be formulated. It is probable that the plan adopted at the Jacksonville, (Fla.) conference, by the Central Competitive Field, will form the basis of the agreement in central Pennsylvania.

Line Forms On Left; Don't Crowd

A Klondike rush to buy western Kentucky coal may—or may not—start, now that R. F. Davis, 1224 South First St., Louisville, Ky., announces that he has perfected a chemical process that will take 2 lb. of silver out of 50 lb. of western Kentucky coal. The lower the grade of coal, the more silver he can get by soaking the coal 15 days in his secret solution. He is surprised, he says, that the chemists have been calling all this silver sulphur, and thinks it is too bad that so many million dollars worth have gone up the flues of the Middle West. Bar silver is quoted nowadays at \$10.30 a pound, but he says he is in no hurry to start a silver soakery, even though he can get \$834 worth of silver out of every ton of coal without hurting the coal much. Market news: West Kentucky mine run \$1.50@1.90.

Nova Scotia Miners Vote to Reject Wage Settlement

Coal miners of District 26 (Nova Scotia) on March 6 voted, 5,617 to 3,145, against acceptance of the wage scale recently negotiated between International officers of the union and the British Empire Steel Corporation. Semi-official reports were in circulation that the union would withdraw from Nova Scotia as a result of this action.

Unions of District 26 have been under a provisional government since last summer, John L. Lewis, president of the International, having ousted the regularly elected officers for calling an allegedly unauthorized strike. The latest suspension occurred in January, causing 12,000 men to remain idle for several weeks and ending when work was resumed under the wage agreement which failed of ratification in the referendum March 6.

Hundreds of Cape Breton coal miners quit work March 7 and a civic holiday was declared in honor of James B. MacLachlan, deposed official of the United Mine Workers, who arrived in Glace Bay on leave from Dorchester penitentiary, where he is serving sentence for sedition in connection with last year's strike.

MacLachlan, secretary, and Dan Lingstone, president, were removed as officials of District 26 at the instance of John L. Lewis, International president of the miners' union, during the 1923 strike. The secretary later was sentenced to two years for having circulated handbills denouncing the government for sending troops to the strike zone.

MacLachlan's arrival at Glace Bay and his trip through the coal fields was a triumphant procession. A thousand miners greeted him with two brass bands and he was formally welcome to each town through which he traveled.

When he reached Sydney he was paraded through the city to Steel Workers' Hall, where the "Red Flag," song of the Third International, was sung.

Watson and McAuliffe Point Out Advantages Of Three-Year Treaty of Peace

Comment of President of Consolidation Coal Co.

In commenting on the Jacksonville agreement it may be wise to distinguish between the contract as a three-year peace treaty and as an economic fact. To avoid another nationwide strike at this time and to provide for uninterrupted production for three years is clearly to the advantage of both the industry and the public. The latter is assured of a continuous supply of coal and is, therefore, without any just cause for complaint. The industry benefits by the fact that those portions of it which can live and prosper only by strikes, shortage and public panic are given no chance to profit at the expense of established enterprises. As a peace measure, therefore, the three-year contract has undoubted benefits.

So far as the economics of the industry are concerned, the three-year truce, if wisely used, can be made to contribute to the future strength and stability of the industry. Though peace between op-

erators and labor in itself alone does not guarantee a prosperous industry, it gives all constructive elements a chance to restore healthy conditions.

Though this process may be temporarily drastic for some, its results, in my judgment, will be beneficial to the industry as a whole. The free play of supply and demand usually has proved a good medicine for industrial ills. In the case of the present coal situation, whatever its temporary phases, the bituminous-coal industry may confidently be expected to retain its place as the country's basic business, fundamentally sound and vital to national prosperity. No temporary ailments can affect the essential work it has always performed, nor can any competitor permanently take its place in the industrial structure.

In my judgment, the clearest road toward profitable business this year, both for individual companies and for producing districts, lies

in the direction of *cheap coal*. This does not mean the saving of a few cents per ton here and there, so much as it means applying every method of economy, efficiency and improved machinery. Those companies and those districts which are so situated as to put these measures most fully into effect will receive returns in proportion to their efforts. In addition, if labor will co-operate in all these economies and adjustments, it also will receive its reward in employment.

During the months ahead, no one expects profits to flow into the treasury without much intelligent selling and operating effort. But for those who offer on the markets the cheapest coal that can be produced under the most improved mining and management there seems no good reason to anticipate other than a normal share in the prosperity of the country as a whole.

C. W. WATSON.

New York City. President

Statement of Union Pacific Coal Co. Head

The three-year contract arranged for at Jacksonville undoubtedly will tend to eliminate surplus mines and mine labor, and most of all will it reduce the cost of coal to the consumer. This will mean financial loss to many companies owning high-cost mines, but that situation is one that the industry has been drifting toward since 1917; in fact before that year.

As to the effect the reconstruction process will have on the mine workers' union, it is hard to predict. Mr. Lewis certainly made a logical, temperate presentation of his wants to the operators, and his arguments were well received, making a deep impression on many accustomed to the old order of affairs.

The operators, as well as their employees, who see failure ahead

of them will be loath to surrender their market and their day's work to other mines where more favorable cost conditions govern and to the competing non-union mines. An "honest to goodness" alliance between the union and union operators; expressed in the taking off of burdensome conditions, the taxes levied in the form of allowances for this and that, obtained by the workers in the past, coupled with a determination on the part of the men to get behind their portion of the industry rather than to harass it, would go far to carry such mines and their man power until the growth in demand for coal would perhaps restore prosperity.

Further progress toward coal-mining composure will automatically come from their gradual use of mechanical loaders and im-

proved forms of mine transportation, and it behooves every operator to give serious attention to this line of endeavor. To venture any sort of prediction concerning coal is dangerous, but I am of the impression that if the rank and file of the workers fail to extend and amplify the apparent new spirit evidenced by their leaders at Jacksonville, the union will gradually suffer internal losses by reason of their men deserting the union mines to take employment in those working without the union. No one will gainsay the fact that union loyalty is built on the foundation of results obtained, and likewise even the dullest man knows that a high day or unit wage without work is an empty sinecure.

Practical Pointers For Electrical And Mechanical Men

Serious Damages Result from Hasty Repairs to Resistance Grids

It is a well known fact that mine locomotive equipment receives less attention and more abuse than any other piece of mining machinery. Locomotives, as a class, have been built very sturdy because of the kind of work they must perform and the bad conditions under which they operate. However, there are many points about locomotive equipment which must be given at least ordinary attention, in order to prevent serious damage or long delays.

One of the worst mine practices is hasty and improper repair of resistance grids. Frequently, resistance banks are exposed to falls of rock, coal and re-tracking equipment carried on the locomotive. In some mines it is not uncommon to find the rheostat very poorly repaired and jumpered by pieces of iron, steel or copper.

When a resistance grid becomes broken, some motormen have deliberately broken other grids in order to temporarily twist the broken parts so as to complete the circuit. Another common practice is to wedge a piece of iron, usually a rail spike, into the broken parts of the resistance.

Such methods as those are often very dangerous to the equipment, cause jerky operation and damage, to say nothing about the possibilities of starting a mine fire. The illustration shows what resulted after a motor runner had forced a mine spike into some

broken grids and turned on the controller of the locomotive. This piece of metal very quickly fused together and soon dropped to the ground between the rails. It is not hard to imagine the fire hazard which very naturally resulted.

So as to eliminate the necessity for such dangerous forms of repair, it would probably be a good plan to equip

Locomotive Resistance Bank Equipped with Extra Terminals

A copper jumper may easily be attached to the spare terminals and an efficient and safe repair quickly made.

resistance banks with several additional terminals so spaced that whenever a grid becomes broken it would be possible to jumper it by inserting a copper wire into two such terminals. This is illustrated in the accompanying sketch. If such a plan were adopted, it would be very easy for the motorman to make a very good repair on the resistance and thus not be troubled with the frequent delays that usually occur when makeshift repairs are made.

Novel Method Will Be Used To Anchor Power Towers

A unique method of anchorage will be used to anchor the steel towers of the new \$1,250,000 electric transmission line to be built by the Illinois Power & Light Corporation from the power dam at Keokuk, Iowa, to Galesburg, Ill.

A hole 8 ft. deep and 5½ in. in diameter will be drilled where each leg of a tower is to stand. Dynamite will then be lowered into the hole and touched off, blowing a cavity at the bottom two feet in diameter. Concrete will be poured into the cavity and the legs of the tower set into it. After the concrete hardens, the tower legs will be anchored in solid balls of stone im-

bedded in walls of earth compressed by the exploded dynamite.

This will be the first trial, it is said, of the new anchor construction in Illinois, but one now being used in all modern building of steel transmission lines.

Material for the new line has been contracted for by the Illinois Power and Light Corporation. The Blaw-Knox Company, Pittsburgh, will furnish the steel towers; the Aluminum Company of America, Messina, N. Y., the wire; and the Westinghouse Electric & Manufacturing Co., East Pittsburgh, the insulators.

Hints on Coal Analyses for Clinkering Temperatures

The determination of the fusibility of coal ash has become increasingly important in recent years. Especially is this so in relation to the operation of mechanical stokers and production of gas. The composition of the ash is often far more important than the amount.

Alumina is the most refractory constituent of ash and its fusing point, 2,000 deg. C., is lowered proportionately to the amounts of alkalis, silica, and iron present. In many coals the amounts of all but the latter do not lower the fusing point sufficiently to cause great trouble; that is, below 1,400 deg. C. At this point, the amount of iron becomes of supreme importance, as is distinctly shown in the classification of coals such as white and red ash. The technical composition of the iron is of great importance also, as in the ferrous state it lowers the fusion point greatly while in the ferric state, it has but slight effect. The influence of sulphur upon fusing point probably depends upon the accompanying presence of iron as pyrites. In the presence of burning carbon, the ferric oxide may or may not be reduced to ferrous oxide, according to the amount of oxygen supplied and the care of the fire. This no doubt explains discrepancies occurring between actual clinkering of the coal on the grates and the fusing point as determined in a laboratory furnace. For the same reason the fusing point will be found to vary in different types of laboratory furnaces. Therefore, we should deem it advisable to choose such furnaces for laboratory tests as will give reducing atmospheres and hence lower the fusing point, indicating the proper results.

When a test is being made the coal should be burned to ash in clay dishes at as low a temperature as possible; then moistened with water and moulded

What Resulted from a Hasty Repair To a Resistance Bank

After the spike was driven between the resistance grids, the power was turned on and this hot molten mass fell to the ground. Obviously a serious mine fire might have resulted.

into the shape of a Seger cone ($\frac{1}{2}$ in. x 2 in.) by pressing into a mould that may be conveniently made of lead. A piece of thin paper may be moistened and laid in the mould to facilitate removal of the cone. Some coals may require a binder which may be made of a 10 per cent dextrin paste, although this is rarely necessary. The use of smaller cones has recently been advocated.

The cones may be set in triangular holes in a Dixon graphite block and placed in the furnace so as to stand horizontally. This position gives as concordant results as the vertical position and probably more accurate. The fusing point is noted when the cone droops to a vertical position. Care must be taken that the temperature does not rise too rapidly when nearing the fusing point. Satisfactory results may be obtained with a rise of about 5 deg. C. per minute. As reducing atmos-

pheres preclude the use of metallic couples at high temperatures, the temperature may be conveniently read by a fixed-focus total-reduction pyrometer or an optical pyrometer of the Wanner type.

Several furnaces for high temperatures, suitable for the laboratory, are on the market, and a very convenient one for the test just described is the Hoskins Electric Furnace. Heat is generated by means of a heavy alternating current of low voltage passing through a series of carbon plates. This furnace uses a standard 60-cycle supply of current at 220 volts, and consumes about 40 amperes. By the aid of an air-cooled transformer, the voltage is lowered to a pressure of 10 volts. The maximum temperature produced by this furnace is about 2,000 deg. C.

Electrical and Chemical Engineer.
Cleveland, Ohio.

Results of Study of Corrosive Action of Mine Water

Probably the most important corrosion problem to the mine operator is that of pumping equipment. Pumps which may give excellent service under ordinary conditions, where the mechanical strength, workability and other physical properties are the only factors to be considered, may not resist the action of acid mine water. Brass and bronze, as well as ordinary cast-iron and ordinary steel, corrode rapidly in acid mine water.

In many mines it has been the practice to babbitt the pump chambers. This will partially solve the problem, but is not entirely satisfactory for mechanical reasons. Lead-lined chambers give good service, if the lining is tight against the outer wall and does not permit leaks. Porcelain plungers are giving good service, and, if properly cared for, may be safely substituted for the brass and bronze or cast-iron. One advantage in the use of porcelain plungers is that packing troubles can be reduced if this type of plunger is placed in the pumps true and level. If there is any appreciable give or flexure after mounting, the porcelain may crack. The shell of porcelain must be attached and held firmly to the plunger rod. If allowed to run "dry" in the pump, it is liable to over-heat and crack.

PACKING TROUBLE ELIMINATED

The connections should be of some proved acid-resisting material. If care is not used in selecting the connections, corrosion may cause the failure of the connecting part, allowing the shell to wiggle and crack. Little packing trouble is encountered with a plunger of this type. If it costs, say, \$150 to install a 10-in. porcelain plunger, and \$125 to repack a pump, it can readily be seen that if packing troubles and "corrosion of plunger" troubles can be reduced, the extra cost is soon made up. The plunger rod may be made of a material such as a high-chromium-nickel-silicon steel. Such a rod was recently removed from a mine pump after four months of service. It had failed at the threads, but not else-

where. On bronze rods it was customary to obtain about one month's service under the same conditions.

Another serious problem is that of the corrosion of pipes. Ordinary iron or steel pipe, or even wrought-iron pipe, does not last long in very acid water. By lining the pipes with wood it is possible to obtain a satisfactory period of service, providing the pipe can be kept on a grade so that there is no trap. Wood pipe will have a tendency to clog up, if a dip or trap of any kind is in the line.

LEAD-LINED PIPES SUGGESTED

Substitutes for the wood-lined pipe or for iron or steel or wrought-iron pipe have been suggested. Lead-lined pipes might be expected to be of value, and would be if the joints were always tight and if no cracks or leaks developed as the result of buckling of the lead lining, or by attrition by sand or other material wearing through the lining. Lead-lined connections at the pumps might be expected to be of value, but the velocity and pressure of the water are high and the joints must be perfect, or leaks result. For pipe of small diameter, all-wood pipes can be used; say, up to four inches in diameter, or even above that, if bored. Stave pipe may fail, because even a tiny leak, or water from outside, may rapidly corrode the binding wire.

On pumps, acid-resisting alloys or porcelain can be substituted for the materials which fail rapidly. In pipelines, wood can be used, but for track corrosion there is nothing cheap enough which can be substituted. Track will corrode very fast if exposed to the action of acid water. Obviously it is expensive to tear up old track and buy and install new track. The remedy for track corrosion seems to lie in grading the track out of the way of the water. Frequently this can be done by shooting down the roof and building a ditch line alongside the track. In many cases the expense of grading would be more than the amount saved, but on main haulage ways care in the grading may save considerable expense.

There are paints which will resist the action of acid water fairly well, if

abrasion and friction or strains do not break the protective film. Of course, paint is widely used, and if properly chosen will aid considerably in lengthening the life of some of the equipment exposed to the action of the acid water.

The corrosion of other equipment, such as shovels, bars, picks, car-wheels, etc., can best be avoided by keeping them out of the water rather than by attempting to substitute a resistant material.

The question as to the effect of acid mine water on concrete, especially when used in dams and stoppings, has not been definitely answered. From such information as is available, it would seem that, if the mixture is correct, there is not much trouble experienced.

ACID NEUTRALIZED WITH LIME

Frequently, it is necessary or desirable to use mine water in the boilers of the power-plant. Of course, if the water is acid it will quickly corrode the boiler tubes unless previously neutralized. This neutralization can be accomplished by treating with lime rock, as is done at the Calumet mine of the H. C. Frick Coke Co. The resulting precipitate finds a limited market.

It has been suggested that if the water were neutralized underground the pumping equipment would not be corroded. Lime-rock and blast-furnace slag have been suggested as suitable neutralizing agents. There are serious objections to attempting to neutralize mine water underground: (1) large settling and overflow tanks are required, which would involve considerable extra expense in excavating the room; (2) water would probably have to be pumped to one central sump before treating, so the corrosion of pumping equipment would be only partly eliminated; (3) the neutralizing agent would have to be taken into the mine and the product of neutralization removed, involving considerable extra transportation or hoisting.

Tinning Stranded Copper Beyond Support

Bad effects often result from tinning stranded copper beyond the point where the joint is made. For example, instead of coming out through the end of the connector, the solder should stop just inside the connector, so that the stresses will not localize on the strands where the tinning stops and where the strands are not supported against vibration.

Problems In Underground Management

Indicating Mine Conditions by Placing Colored Tacks on the Mine Map

Room and Pillar Miners, Heading Men, Pumps, Hoists and Locomotives
Symbolized by Red, Yellow, Green and Other Pins
Spotted at Appropriate Points

BY JEROME C. WHITE
Penker Coal Mining Co.
Portage, Pa.

"Records and reports," says a prominent industrial engineer, "should be immediate, reliable, permanent and accurate." In the coal industry, one of the records which should be describable in these terms should be the mine map. Every mining man recognizes that necessity so its advantages need not be discussed.

On most maps not only is the completed work plotted but the proposed development also, broken lines being used for that purpose. Unfortunately, the map usually lags behind in its record of active workings, and many superintendents and mine foremen correct that deficiency by drawing the extensions in pencil on the blueprint.

Nevertheless, the map thus corrected does not convey information of a much needed character. It does not show, for instance, whether the places are working or standing idle nor the number of men at work at their extension if they are being worked. This can be accomplished by the use of glass-headed tacks or push pins of varied colors. The method of using these pins is susceptible of wide variation and may be expanded in detail as the user becomes adept in the portrayal of information by the means chosen. Any one can use the method I am about to describe which requires nothing more elaborate than the tacks to which I have referred.

Each pin represents a man; a red pin, let us say, represents a miner loading in a room; a green pin, a heading driver, and, a yellow pin, a miner removing a pillar. This system, by the way, has been found to be particularly valuable in widely scattered pillar sections. Any variety or number of different designs can be secured and used, let us say, to show the location of pumps, hoists or any other pieces or machinery that are moved from place to place and that cannot be posted justifiably on a permanent map or are not ordinarily shown thereon. For instance, if desired, it is possible to show the number and type of any locomotive serving any entry or section. Thus the company with which I am connected has a No. 5 locomotive that serves the 5th Left and 1st North headings. Now, a pin bearing the

number 5 can be placed at the opening of each of those headings. Consulting one's notes or memory it is found that locomotive No. 5 is an 8-ton trolley type machine fitted with a cable reel.

Every measuring day the mine foreman can move his "men" forward; but as far as this is concerned he can move them ahead every time he has the necessary measurements which, in the case of important headings, he will receive daily as advances are made. As men quit or are shifted to new positions the pins can be relocated accordingly. The picture presented can be used by the mine foreman or the superintendent to strengthen their arguments that an additional haulage unit or some other piece of equipment is necessary by showing forcefully the density of the workers or the degree of concentration employed.

Though it is admitted that mine foremen and their assistants usually know the mine and carry such facts in their heads, yet the advantage of putting these records in concrete form for the use of every one concerned will be at once appreciated. This information is highly useful on such occasions as the periodic visits of the superintendent, general superintendent, inspectors, etc. Numerous other advantages are possessed by this system, and with the exception of the first work of planning the nomenclature and placing or locating the pins, the total time daily expended in keeping this record abreast of actual work will not be more than five minutes. The total cost for the equipment will not exceed \$5, even for the largest mine. Some soft backing can be used for the mine projection such as pine, wall or beaver board. The pins can be stuck in plaster if necessary.

It should be understood that I am not suggesting this method as a substitute for, or to take the place of, any checking system. I am sure, however, that any one who cares to try it will be pleased with the results. This system is applicable to large and small mines alike, and with it one can quickly, intelligently and forcefully explain his work, methods and progress

and illustrate his explanation to the intelligent understanding of all interested parties.

It has this further advantage, that at a glance it will show to the operating officials in charge all the work in hand, together with its location and progress. This is true visualization. The records are thus immediate, reliable and accurate and the map is permanent. In this respect it puts the mining man on a par with the best of other industrial officials, and if immediately adopted, for the time being at least, will place him who uses it in advance of some of his brother operators.

To Replace Flame Safety Lamp As a Gas Indicator

In order to give the miner the advantage afforded by the use of the flame safety lamp when using electric illumination an instrument known as the "methanometer" has been devised by L. Williams. It consists of a combustion chamber in which the methane in a methane-air mixture under pressure is burned by a heated platinum wire, and a long capillary glass tube containing a column of liquid which rests at one end on the elastic membrane by which the combustion chamber is covered and at the other engages a column of air against the sealed end of the tube. By this column of liquid the changes of volume after combustion are measured, the volumetric changes, of course, corresponding with the percentage of methane in the air.

The instrument acts slowly, for the combustion chamber does not contract promptly but gradually cools. This cooling is, however, sufficiently uniform that allowances can be made for it when calibrating and using the instrument. Thus if the time of heating the wire is five seconds and the time allowed to elapse after the current has been interrupted is always fifteen seconds, constant readings for a given percentage of methane are obtainable.

The British Committee on Miners' Lamps says of this device: "Inasmuch as the principle upon which this instrument works is that of combustion analysis, it will be understood that incorrect readings will be obtained if the inflammable mixture to be analyzed contains more methane than can be burned completely by the oxygen of the air, that is more than 9.45 per cent of methane. This should not militate seriously against its use, which we imagine will be mainly for the determination of small percentages of methane that cannot be estimated accurately with the flame safety lamp."

Production And the Market

Waiting Game Is Policy in Soft-Coal Market; Consumers Seem to Hold Off for Inducements

A disposition to hold back prevails throughout the coal trade. The habit at this time of year of "laying low" to see what will happen April 1 has grown to such a degree that it is observed as a sort of ritual. There is no doubt, however, that the action of the miners in voting March 12 on the Jacksonville agreement is awaited with interest. Then too, wage agreements are still to be negotiated in the Kanawha field, western Kentucky, central Pennsylvania and northern West Virginia. Meetings to draw up pacts in the latter two districts are about to be held.

In some regions consumers are waiting for new price circulars to appear before committing themselves, continued mild weather aiding and abetting them in their policy of "playing safe." In some quarters there is a strong belief that a favorable attitude by government authorities toward the compilation of trade statistics is one of the greatest needs of the coal industry at this time with the keenest kind of competition looming ahead.

Coal Age Index declined 2 points to 181, as of March 8, the corresponding average price being \$2.18. This compares with \$2.21 on March 1.

Midwest Sogginess Unrelieved

Even the most optimistic seller of coal in the Middle West can see little cause for encouragement in the present condition of the market. The usual slowing down of domestic business is in evidence and even steam coals, which were on the upgrade a week ago, have softened a little. Only one railroad, the Grand Trunk, has invited bids on fuel for the year, nor does industry show a disposition to let long-term contracts, though the operators show a real willingness to sign them up.

Big consumers seem to have adopted a program of keeping the producers on the anxious seat for awhile, with the apparent hope of being offered inducements to come in. Prices in the southern Illinois and Mt. Olive fields have fallen sharply and a number of mines in the Standard field have suspended for lack of business.

Western Kentucky Maintains Values

Operators in western Kentucky are maintaining values despite discouraging competition from non-union fields and strip operations. A strike is likely in April that will affect more than half the field's output.

Northwestern consumers shrewdly wait, with soft spring weather prevailing and a heavy supply on the docks, some of which may have to be moved in a hurry before the navigation season opens. Power companies seem to be the only buyers, some large orders having been placed to make up for lack of water power. Mines in the Southwest are working only a little better than half of normal, with a growing accumulation of lump and nut "no bills" and a shading of list prices on domestic grades.

The Ohio trade is completely at sea over the new conditions prevailing in the market. Dullness reigns in the Pittsburgh and central Pennsylvania markets. New England reports no new developments to relieve the funereal calm that has settled over the market. Dealers in Atlantic seaboard markets find customers scarce.

Bituminous coal produced during the week ended March 1 totaled 10,705,000 net tons, according to the Geological Survey, an increase of 338,000 tons compared with the previous week, which was a holiday week, but a decrease of 434,000 tons from the week ended Feb.

16. Production of anthracite also recovered, 1,866,000 net tons being produced, compared with 1,655,000 tons during the preceding week and 1,900,000 tons in the week ended Feb. 16.

Midwest Markets Soft

Nothing came along through the Midwest during the past week to bring much relief to the soggy condition of the market for all coals. Even steam coals, which were on the rise a week ago, seem to have overstepped themselves and softened a little during the last days of the week. Southern Illinois and Fourth Vein Indiana, which showed signs of passing \$2, settled back to \$1.75@\$.1.90 and central Illinois and Fifth Vein Indiana range from \$1.75 down to \$1.50.

Domestic business on all coals continues slowly to slow down toward the customary May low speed. The Franklin County Operators' Association has not yet announced its new circular, however, and this appears to have prevented others from doing so. It is expected that southern Illinois lump, which sets the pace for the Midwest, will drop a cold dollar from \$3.75. As the market stands now, some of it already moves at \$2.75.

A real willingness on the part of Midwest operators

to make long-term contracts has not rounded up much business. Only the Grand Trunk, among the railroads, has invited bids on the year's business. Most of the others appear ready to live for awhile on the stockpiles they bought last summer. There is no rush of industry to contract yet, either. "Let's wait until these operators have suffered awhile; then we'll get a price," is a common program.

In all southern Illinois fields a noticeable decline in business is in evidence. Operators generally are offering lump and egg at prices ranging \$2.85@\$.3, while nut is being offered at \$2.75, but orders are being taken for as low as \$2.50. In the Mt. Olive field lump prices have been reduced from \$3.25 to \$3, with very little demand. Screenings have advanced 25c. per ton and are being offered at \$1.50@\$.1.60. Other steam sizes, however, are sluggish. In the Standard field a number of mines have suspended, and most of those operating find it difficult to move prepared sizes at any price.

Mild weather, which has prevailed for the past week, has caused St. Louis consumers to withhold orders, expecting a price drop April 1. Local demand for screenings is good and dealers having storage space for their forkings are holding them rather than selling them, since every indication points to higher prices on fine sizes. Country domestic trade is flat.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	March 10 1924	March 3 1924	Feb. 25 1924	March 12 1924
Index	181	183	184	268
Weighted average price	\$2.18	\$2.21	\$2.23	\$3.24

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

West Kentucky Faces Trouble

Although demand is off and western Kentucky operators are not loading out any large quantity of coal it can truthfully be said that the operators are maintaining values in the face of rather hard competition from non-union fields and strip mines. Demand for prepared coal has slumped, causing some cancellations and rejections, but production of screenings has been small, and prices have advanced to \$1.25@\$1.40 asked for pea and slack and nut and slack. Prepared sizes continue steady, with block at \$2.7@\$3; lump and egg, \$2.40@\$2.75; nut, \$1.75@\$2.25. Mine run is quoted at \$1.50@\$1.90, but some stripper mine run has been quoted as low as \$1.30, it is reported.

There is every indication that production of the field will be materially reduced in April, as there are indications that there will be a strike, which will affect more than half the production of the field. Ordinarily this would tend to force prices upward, but as it will come at a dull season, it probably will affect only screenings to any material extent.

Prices have weakened about 25c. a ton on all sizes in the eastern Kentucky field over the week. Operations in most of the state fields have slumped and there are not

many mines with much business on their books, while cancellations and rejections on account of warmer weather and lower markets have resulted in more coal on track. It is doubtful whether any coal is being quoted at over \$3.25 a ton today, while some screenings are offered as low as 90c. for nut and slack in the Hazard field.

Northwest Awaits Price Cuts

A softening all along the line was noticeable throughout the Northwest during the past week, although no changes in prices have been announced. This applies to the Head-of-the-Lakes and all the way down to Milwaukee, where soft spring weather did its worst. The supply on hand on the docks is heavy and buyers wait shrewdly. Some of it may have to be moved hurriedly before the spring navigation season opens.

At Duluth Youghioghenny and Hocking were especially weak. About the only customers now are the power companies, which are placing large orders to make up for the lack of water power. The Northern States Power Co. is reported to have contracted for 30,000 tons recently, and to have had the shipment sent to the Twin Cities. Ordinarily these companies would be buying no coal.

A relatively good demand for Pocahontas exists. This is because of the scarcity of desirable hard coal and its high price. The use as a substitute for househeating is the only reason for the demand for Pocahontas.

Official figures of shipments from the docks in February have not been announced, but it is safe to say that the number of cars from the Head-of-the-Lakes will not be more than 14,000. This is practically the same as in February last year and compares most unfavorably with the 25,000 odd cars shipped here in January of this year.

Little Doing in the West

Strengthening of the demand for screenings with an accompanying weakening of the demand for lump and slack resulted in an advance of 25c. a ton on Kansas screenings, to \$2.50, March 1. Mines in the Southwest are working from 50 to 60 per cent of normal, with a steadily growing accumulation of lump and nut "no bills." Shading of list prices on domestic grades continues to increase as the market falls off. Kansas coal is quoted at \$5 for lump; \$4.50 for nut, \$3.25 to \$3.50 for mine run and \$2.50 for screenings.

The market in Colorado is low. The working time dropped to an average of twenty-four hours per mine last week. The chief point of interest is the reduction on March 1 in the prices on all coals from northern Colorado, Crested Butte and Canon City districts. These prices are absolutely the lowest that have ever been quoted from these fields, considering the cost of production. Walsenburg and Canon City lump and nut are \$4.25 and \$3.75 respectively, Trinidad lump and nut are both \$3.50, and Crested Butte anthracite furnace and baseburner sizes are \$6.50.

Utah mines do well to get two days a week nowadays. The heavy cut in prices on domestic two weeks ago produced little business. Low mine production has boosted slack 25c., however, to \$1.50, with screened slack \$2.

Ohio Trade All at Sea

At Cincinnati the whole price line-up shivered this week with the impact of overproduction and disinterestedness of buyers. From top to bottom—from the top grade of specialized coals to the lowliest of the slacks—the shock had a telling effect. The result is that the trade is completely at sea. Coal on consignment has been clogging the avenues of trade for the past week. Again the purchasing agents of large plants north and west from here are using the most effective weapon in their hands—rejections. And while this liquid tonnage is only a small percentage of the total going through this gateway, yet it is, in truth, creating the market price and settling the values in its time accustomed way. Lake buyers are coy—they are not in the market and even tempting offers of price to extend over several months has not caused them to rush in. Slack prices have slid off this week in a surprising way in view of the fact that domestic, egg and other sizes are below normal in the making. Domestic naturally is soft with the retailers refusing to load up with more than immediate requirements. The increase in the make and take out of the smokeless, also has softened that market. There has

been no change in the retail situation. Specialized coals are quoted at \$2.75@3 for egg and \$3.50@4 for block.

The Cleveland market is simply marking time until some of the stockpiles accumulated in anticipation of labor difficulties are used up. Steam consumers generally still have thirty to sixty days' supply on hand, the railroads have ample fuel and are taking only a minimum amount at this time, and public utilities are heavily stocked. Therefore, the producer is receiving little inquiry for fuel and the market is more dull than it has been in many months.

Quiet prevails in all branches of the coal trade in Columbus. Both steam and domestic buyers are using caution in placing orders and there is no disposition to increase stocks under present conditions. This is seen most strikingly in the steam trade, where many large users had accumulated stocks in anticipation of a suspension. With the settlement of the wage scale these users shut off orders and are now gradually reducing reserves. This is having its effect on trade and buying is limited to only a small amount sold off the open market to fill in or where prices have been made attractive. Utilities are not buying to any extent and the same is true of railroads. Iron and steel plants are taking some tonnage, but not sufficient to cause much stir in the market.

The spot market at Pittsburgh is extremely dull, but this makes little difference as at no time recently has there been much tonnage moving in the spot market. The chief movement has been on regular contracts for the coal year and on less formal arrangements whereby shipments were continued and prices were agreed upon periodically, generally from month to month. Spot prices show no change except for a decline in slack. In mine-run and lump operators are simply holding prices, despite the light demand in the spot market, as they see no advantage in cutting. Operators report that there has been little if any decrease in coal production in the Pittsburgh district in the past two or three weeks.

Operators in central Pennsylvania report a dull market, with prices low. Manufacturing plants generally have a sixty-day supply of fuel on hand. Contract prices range from \$2.10 to \$3.

Demand at Buffalo is up to normal and promises to continue so right along, but output still is in excess of needs, and so long as that lasts the market must remain dull.

Inquiry Lacking in New England

In New England the past week brought forth no new developments whatever. Both all-rail and by water there is a dearth of inquiry, and shippers are hard put to it to find places for coal. Practically every large consumer is determined to let his present stock run down to the narrowest prudent margin, and certainly in the current situation there is no inducement to make purchases much in advance of actual consumption.

In the smokeless districts mining is barely on a 40-per cent basis, and except for certain contract requirements there is nothing even approaching stable demand. The Virginian piers have a reasonably large supply on hand, but few agencies now care to take the chance of sending coal down more than a short time in advance of requirements. Coastwise trade is dull, and offshore there is relatively little tonnage moving. From day to day there are occasional inquiries for spot cargoes, and on these the price varies from \$4.60 to \$4.80 per gross ton f.o.b. vessel. No. 1 Navy Standard Pocahontas and New River are selling at \$4.70@4.75, but among buyers here there is a feeling

that quotations are bound to be lower later in the month, a \$4.50 level being anticipated for April. This would make the net price at the mines somewhat less than \$2 per gross ton, and should any such price carry through it is easy to see there will be only a very restricted market in New England for coals other than Pocahontas and New River.

The all-rail situation shows no hopeful sign. East of the Connecticut River, smokeless shippers have every reason to expect that they will have the call, and so long as railroad tariffs are maintained on their present scale central Pennsylvania tonnage reaching this market is certain to be small. Both at New York and at Philadelphia only minimum tonnages are being dumped over railroad piers, and in this market Pennsylvania coal even by water is seldom heard from.

Inactivity Prevails in Seaboard Markets

The recent condition of inactivity in the Atlantic seaboard markets still prevails. New York dealers are order hunting, but with indifferent success. At Philadelphia the trade runs along quietly, there no longer being any disturbing factor to cause the consumer to be anxious about his future coal supply. While this market has shown no outward signs of taking an unusual tonnage since the first of the year, still much coal has been moved. The price situation is unchanged, there having been little variation for a couple of months.

Feelers for contracts have appeared at Baltimore. Closings on this class of business are not heavy as yet, but there are signs that the policy of purchasing in the open market at prices still some 15c. off the spot level is beginning to break. A meeting of representatives of the Monongahela Coal Association, the Northern West Virginia Coal Operators' Association and the United Mine Workers to be held in Baltimore during the coming week is expected to settle the wage situation in northern West Virginia for the period after April 1.

Various factors have combined to depress prices not only of high-volatile but of low-volatile coals as well in West Virginia since the first of March. Settlement of the wage controversy, milder weather and a material increase in the car supply have all been factors tending to weaken prices owing to the fact that buying is on a limited scale and fuel supplies at the mines and in the market are plentiful.

Anthracite Now a Weather Proposition

With spring officially only two weeks off, the anthracite situation in New York is swayed by temperature—if not temperament. Stove is in good demand; but some of the yards have none. Some companies are breaking egg to stove and nut sizes.

March having been quite mild thus far, the Philadelphia consumer is doing his best to get by the balance of the season with as little coal as possible. Dealers do not have the least trouble now to get all the coal they want, and of any size; just now they seem to be trying to manipulate their stocks so as not to have an excess on hand when April 1 arrives. Similar conditions prevail in Baltimore.

Foreign Market And Export News

British Coal Market Shows Firm Tendency; Output Declines Slightly

The firmness of the Welsh coal market is very well maintained, probably due to the fact that the collieries are still in arrears owing to the rail and dock strikes. As a result many Continental buyers are clamoring for coal, fearing a miners' strike in April and desiring to lay in stocks. There are rumors that much business has gone to America and Germany because of the tardiness of Welsh deliveries. The Italian and Near East business has fallen off, though the demand from South America is satisfactory. The Egyptian State Rys. has purchased 50,000 tons of steam coals.

Coal production at British mines during the week ended Feb. 23, a special cable to *Coal Age* states, totaled 5,802,000 tons, according to the official reports. This was a decline of 19,000 tons from the week ended Feb. 16, when 5,821,000 tons was produced.

The situation in Newcastle is unchanged though prices are showing a tendency to rise. Though the dock strike introduced an element of doubt on the part of buyers, the collieries kept busy clearing off arrears.

Negotiations between the miners and the colliery owners were resumed on March 6 and there is good reason to hope that a mutually satisfactory basis for a new wage agreement will be arrived at before the expiration of the present one, on April 17.

Market Tone at Hampton Roads Dull; Prices Tend Downward

Business at Hampton Roads shows little change, with considerable movement in all branches of trade, but practically all activity on direct orders or old contracts. Spot business is dull, and prices show a downward tendency.

Actual movement is fairly heavy, coastwise, foreign and in the bunker trade. Italy is getting a big share of the movement, while several large car-

goes were noted bound for French ports. The tone of the market is dull.

Increase in general shipping continues to affect the bunker trade, and the outlook is pronounced by shippers to be bright. No big contracts have been reported, though several were rumored.

French Industrial Inquiry Brisk; Domestic Demand Better

Industrials, anxious to escape the high prices for British coal, are taking to French coal whenever possible. Inquiries are in greater volume than production. The demand for house coals also has increased, due to the cold weather.

The 3 fr. cut in coal prices is now applied in all the mines, except the Houve and Petite Rosselle collieries, in Lorraine, and the Mines Domaniales de la Sarre.

French consumption of Sarre coal has increased, having now reached an average of 45 per cent of the capacity of the field, compared to 30 per cent in 1921.

In the matter of indemnity fuels the Office des Houillères Sinistrées is not filing any new orders, only furnishing coal on contracts in course of execution. Prices remain unaltered.

Coke deliveries continue to come through in fair volume. Renewal of the agreements for the delivery of indemnity fuels expiring on April 15 is now being discussed between the Inter-Allied Mission and German industrials.

Traffic News

Indiana Intrastate Rates

Drop April 1

An advance copy of the decision of the Public Service Commission, which orders a reduction in the rates on bituminous coal from Indiana mines to practically all consuming points within the state, has been received by Jonas Waffle, secretary of the Indiana Coal Traffic Bureau. The order requires the carriers to establish the reduced rates effective April 1, 1924. The extent to which reductions will be made from the Linton and Clinton groups to typical consuming points is shown in the following statement:

	Brazil-Clinton		Linton-Sullivan	
	Old Rate	New Rate	Old Rate	New Rate
Anderson.....	\$1.58	\$1.48	\$1.58	\$1.48
Angola.....	2.36	1.90	2.46	2.00
Bloomington.....	1.51	.95	1.13	.95
Connersville.....	1.70	1.48	1.70	1.48
Fort Wayne.....	1.76	1.65	1.81	1.75
Greencastle.....	1.13	.95	1.13	.95
Lafayette.....	1.45	1.38	1.55	1.38
Michigan City.....	1.70	1.60	1.80	1.70
Muncie.....	1.58	1.48	1.58	1.48
Stroh.....	2.33	1.90	2.43	2.00
Union City.....	1.76	1.58	1.76	1.20
West Lebanon.....	1.45	1.20	1.55	1.20

Mr. Waffle states that while the reductions ordered by the commission are somewhat less than those suggested at the hearing, the new rates will be a big improvement over the present adjustment and will eliminate to some extent the discrimination which exists between the Indiana rates, on the one hand, and those from the Eastern producing fields on the other.

Assigned-Car Order Postponed Yet Again

The Interstate Commerce Commission has again postponed the effective date of its order restricting the use of assigned cars to bituminous-coal mines from April 1 to June 1, 1924. This is the seventh postponement of the order.

To Discuss Lignite Rates

Rates on lignite from points of origin in North Dakota to points of destinations in South Dakota and Minnesota as well as to intrastate destinations, will be discussed at an Interstate Commerce Commission hearing to be held in Bismarck, N. D., April 21. Examiner Wagner will preside.

Frisco About to Build Nine-Mile Cut-Off

The Frisco railroad will begin construction this spring of the nine-mile cut-off from Schuster, Okla., through the new coal field west of Henryetta, Okla., to again connect with its main line at Creek mine on the south according to report. The survey of this line was made and the right of way purchased last summer. This cut-off will open up the new coal field on the west-

ern limits of Henryetta. This report previously has been regarded merely as a device to keep the M. K. & T. out of Henryetta. An application by the M. K. & T. road is now before the Interstate Commerce Commission seeking an extension of its line from Oktaha to a junction with the Okmulgee Northern short line, which would be extended to Henryetta. The coal west of Henryetta is said to be much harder than that produced closer to town, and has no middle band, thus permitting it to be mined at less expense.

Virginian and N. & W. Cuts Rates to Washington

It has been announced by the Virginian and the Norfolk & Western rys. that the rate on coal from mines on those roads to Washington will at once be established at \$2.84 per gross ton. Shippers in the New River district have been enjoying the same rate for some time over the Chesapeake & Ohio. The action of the Norfolk & Western and the Virginian simply puts the Washington rate on a parity with the rate already established by the Chesapeake & Ohio.

C. & O. Reduces Rates Outside New River Field

Freight rates on coal from points on the Chesapeake & Ohio other than the New River field have been reduced to the extent of 5c. a ton, as the result of a conference between W. P. Tingley, manager of the traffic department of the Jobbers and Manufacturers bureau of the Huntington Chamber of Commerce, and A. P. Gilbert, general freight agent of the road. The new rate will be \$1.08 per ton instead of \$1.13 and the new rate into Huntington from the New River district will be \$1.28 per ton instead of \$1.33, which previously prevailed.

It is estimated that the reduction will result in a saving of at least \$5,000 a year to the users of coal in Huntington. In Kenova it is estimated that from 160,000 to 170,000 tons of coal yearly are consumed, so that industries in the city named will effect a saving of from \$8,000 to \$8,500 per year.

Southern Roads Plan Betterments

The Central of Georgia Ry. will expend from \$5,000,000 to \$6,000,000 in eliminating heavy grades, sharp curves and grade crossings on its line between Birmingham, Ala., and Columbus, Ga., contracts to be let about April 1.

The Southern Ry. will begin work at an early date installing a complete block system of signals between Birmingham and Atlanta. A telephone line also will be constructed which will carry a double circuit for use in dispatching trains and another line for miscellaneous company business.

W. D. Beck Moves Up

W. D. Beck, having been appointed chairman of the Chicago Operating Committee, American Railway Association, also has been appointed district manager and manager refrigerator department of the Car Service Division, in place of J. M. Egan, resigned, to accept position of vice president, Missouri Pacific R.R. The change became effective March 1, 1924.

Would Build New 16-Mile Line In Cambria County, Pa.

The Conemaugh & Blacklick R.R. has applied to the Interstate Commerce Commission for permission to issue \$1,000,000 of capital stock, the proceeds to be used in the construction of sixteen miles of new line in Cambria County, Pennsylvania.

Obituary

Morgan R. Morgan, aged 76, one of the best known mining men in the Wyoming Valley, Pennsylvania, died March 8 at the City Hospital, Wilkes-Barre, Pa., following a six months' illness of diabetes. For many years Mr. Morgan was general inside superintendent of the Lehigh Valley Coal Co. in charge of the Wyoming Valley operations. He retired from active duty about five years ago. Mr. Morgan was born in Llandoverly, Wales, in 1848, and came to America in 1867, settling in the Wyoming Valley, where he was first employed as a miner at the Empire Colliery. In 1887 he was made mine foreman of the Wanamie and Stanton mines of the Lehigh & Wilkes-Barre Coal Co., and in 1891 became general superintendent.

Robert L. Hearon, 59, traffic manager of the Colorado Fuel & Iron Co. and vice-president and general manager of the Colorado & Wyoming Railway Co., died in Pueblo, Colo., March 1 after a long illness. He had been traffic manager for the fuel and iron company since 1907.

Coming Meetings

New England Coal Dealers' Association. Annual meeting March 20-21, Boston, Mass. President, W. A. Clark, Boston, Mass.

Association of Iron and Steel Electrical Engineers. Fuel Saving Conference, April 2 and 3, William Penn Hotel, Pittsburgh, Pa. Secretary, J. F. Kelly, Empire Bldg., Pittsburgh, Pa.

Canadian Retail Coal Association. Annual meeting, April 3 and 4, King Edward Hotel, Toronto, Ont., Can. Secretary, B. A. Caspell, Brantford, Can.

American Institute of Electrical Engineers. Spring convention, April 7-10, Birmingham, Ala. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

American Welding Society. Annual meeting, April 22-24, Engineering Societies Building, 33 West 39th St., New York City. Secretary, W. M. Kelly, 33 West 39th St., New York City.

National Exposition of Coal Mining Equipment and Machinery of the American Mining Congress, May 12-17, Cincinnati, in conjunction with the annual meeting of the National Coal Association.

National Coal Association. Annual meeting, May 14-16, Cincinnati, Ohio. Executive Secretary, H. L. Gandy, Southern Building, Washington, D. C.

International Railway Fuel Association. Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

The American Society of Mechanical Engineers. Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

News Items From Field and Trade

ALABAMA

A report from Gadsden is to the effect that a \$25,000,000 St. Louis syndicate is negotiating for the purchase of 25,000 acres of coal and ore lands in Etowah and DeKalb counties, the same company having recently acquired 41,000 acres of these mineral properties in Marshall County. It is reported that the erection of several furnaces near Attalla is contemplated and also on the Tennessee River, near Guntersville. It is said that plans are under way in connection with the Scullin Steel Co., of St. Louis, to develop that city as a steel-making center.

Organization of the Deep Water Coal Co., with a capital of \$15,000,000 was announced at Birmingham, March 1. L. B. Musgrove, of Jasper, Ala.; C. A. Meade, formerly vice-president of the DuPont Powder Co., and C. A. Lask, New York attorney and capitalist, are the three leading officials of the new company, which recently purchased 500,000 acres of coal lands in Jefferson, Walker and Winston Counties. The main office will be at Jasper. Mr. Musgrove said this will be one of the largest coal companies in the United States. Tipples will be constructed immediately, and Mr. Musgrove thought that the company would be in operation soon.

ALASKA

Complete electrification of the Evan Jones mine, in the Matanuska field, will soon make that the most modern coal mine in Alaska. A tunnel 1,300 ft. long will be driven from the bunkers at the foot of the hill directly into the underground workings, eliminating a slope. The mine is owned by Oscar Anderson, Z. J. Loussac and Jack Collins.

COLORADO

The Crown Fuel Co., with mines in the northern Colorado lignite fields, paid \$6,604 in back wages to ninety miners in the Crown mine at Marshall, last week. These settlements came about through the combined efforts of the State Industrial Commission and the Attorney General's office, after the case was placed before them by the men. When the miners were not paid, they refused to work on Feb. 2, conducted a mass meeting and sent representatives to place their case before the state officials. According to the members of the Industrial Commission the miners will return to work immediately.

The new Oliver Fuel & Coal Products Co. mainly made up of Kansas City, Mo., capital, has organized to develop coal land near Paonia, in the Canon City field.

ILLINOIS

The Chicago Section of the American Institute of Mining Engineers, held its annual election on Feb. 14, at which time the following officers were elected for the ensuing year: Chairman, John A. Garcia, vice chairman W. R. Wright, secretary-treasurer, Keith Roberts, executive committee members, H. T. Walsh and H. P. Gillette.

A new mining record was set for Saline County when on Feb. 28 the Harco mine of the Harrisburg Colliery Co. hoisted, screened and loaded into railroad cars 4,730 tons of coal in eight hours. This surpasses the previous Saline County record by 593 tons. It was only recently that Big Creek No. 3 mine hoisted 4,187 tons of coal in eight hours, taking the honors previously held by the Harco mine by 25 tons.

The Andrew mine of the Springfield District Coal Co. has been closed for an indefinite period, laying off 250 men.

Prepared to spend a half million dollars in its development, the Crerar-Clinch Coal Co., of Chicago, has completed plans for the opening of a new strip mine on an acreage about two miles north of Du Quoin. The operating company is the new Gayle Coal Co. The company has purchased 133 acres of land located immediately on the east side of the main line of the Illinois Central right of way, and is a part of the old Williams and Henry H. Kimmel farms. The vein underlying is 6 ft. and over in thick-

ness with about 25 to 28 ft. of overburden. The equipment will be electrically operated. The Illinois Central has begun construction of the switch and it is estimated that approximately three miles of track will be used in handling the output of the strip mine when operating. Elmer Mayor, of Du Quoin, will have charge of the operations at the new strip pit. This is the third new strip mine in the Du Quoin district. The other two are the mines of the Scott, Smith Coal Co., a large stripping concern just south of Du Quoin, and of the Hartshorn Coal Co. just west of Elkhartsville, controlled by the Hartshorn interests, of Danville.

F. F. Green, of Christopher, who was chief engineer, has been promoted to be superintendent of the Valier Coal Co.'s mine at Valier. Charles E. Anderson also of Christopher, who was former mine manager when the New North mine of the Old Ben Coal Co. reached its highest record in tonnage output, has been appointed as mine manager for the Valier mine.

INDIANA

Are railroads in Indiana weighing coal shipments as required by law? The Indiana Coal Merchants Service Bureau, Inc., acting for six complaining coal companies of Indianapolis argued before the I. C. C. in a recent hearing, that the Monon, Big Four and Nickel Plate railroads are not, and that, as a result, coal is billed by the roads at excessive weights and these errors were not corrected. A commission report is expected early in the summer.

Three shifts of men are working on the bottom of Francisco mine No. 2, which was opened recently near Princeton, after having been closed for several weeks because of a fire. Falls of slate in different parts of the mine caused the most damage. The debris is being cleaned away and port timbers replaced. The mine will be ready to resume operations this week.

Walter Bledsoe & Co., recently added the Ventura coal mine in Indiana, on the Big Four railroad, to its list of collieries. The new mine has a daily capacity of 1,500 tons and its coal is No. 5, seam.

Union miners in District 11, which includes all the Indiana coal field except the block coal district, which is No. 8, held a district convention in Terre Haute, March 11. Only matters pertaining to the district organization and constitution were discussed. John Hessler, of Terre Haute, is president of the district, and William Mitch, also of Terre Haute, is secretary-treasurer.

IOWA

Many small coal mines of southern Iowa would be saved the expense of constructing a second opening to their shafts by an amendment to the Senate to the general mining law. The House of Representatives has passed an amendment providing that all mines should have at least two exits for safety purposes, but Senator Shane, of Wapello County, successfully sponsored an additional clause, giving the mine inspector discretion as to the enforcement of this section in the case of small mines, where only a few are employed. Without this amendment, he contended, the new law would work a hardship on many small companies.

The Shuler Coal Co., with mines at Alpha, Ill., has opened offices at 506 Kuhl Building, Davenport. S. K. Marsh has been appointed manager of the Davenport office.

KENTUCKY

The federal court at Maysville, recently issued a temporary injunction against striking employees of the Liberty Coal & Coke Co., Pineville, to prevent them from interfering with the company, or carrying out alleged threats of violence. Thirty-eight workers, members of the United Mine Workers of America, and President John L. Lewis, are named in the order. The miners went out on strike over a disagreement as to wages.

Following a meeting of the board of directors of the Reinecke Coal Co., Madisonville, on Feb. 26, a statement was

issued to the effect that it had been decided to close down the mines for an indefinite period due to high production cost, low prices and inability to operate profitably under existing conditions.

Involuntary bankruptcy proceedings have been instituted at Covington against the Green Rock Coal Co., of Riceville, and the Harlan Co-operative Coal Co., of Harlan.

The Storm King Coal Co., at Storm King, on the L. & N. RR., near Whitesburg, closed down indefinitely on March 1 following six months of unprofitable operation. Over 150 men are employed in the mines.

MICHIGAN

The firm of Charles A. Floyd & Co. has been organized for the purpose of handling securities, particularly in connection with coal properties and the coal business with offices in the Dime Bank Building, Detroit. The company is capitalized at \$50,000 and the officers are as follows: Charles A. Floyd, president of Kennedy, Floyd & Co., president; A. H. Green, Jr., president of Charcoal Iron Co. of America, vice-president; H. J. Eckenrode, president of the National Plate Glass Co., secretary and treasurer; Merlin Wiley, formerly Attorney General of the State of Michigan, general counsel.

The new representative of the Falk Corporation in Detroit is Charles C. Walsh, 1500 Real Estate Exchange Bldg. He will sell Falk herringbone gears and Falk-Bibby flexible couplings.

MISSOURI

In an effort to find a domestic market in St. Louis for their coke, the St. Louis Coke & Chemical Co., with plants in Granite City, has opened up sales office with H. S. Graves in charge, formerly of the Graves Coal & Coke Co.

The Mitchell & Lovell Coal Co. has closed the mine known as the old Mitchell mine but is placing additional men in the Busy Bee mine as fast as possible.

NEW YORK

Bids have been requested by the New York, Susquehanna & Western R.R. for 32,240 gross tons of No. 1 buckwheat, to be delivered as may be designated during the period April 1, 1924, to March 31, 1925. Bids are to be submitted by noon, March 19.

The Erie R.R. has asked for bids for its coal requirements during the period April 1, 1924, to March 31, 1925, proposals to be submitted not later than noon, March 19. The requirements consist of 1,040 gross tons grate coal; 500 tons each of egg and stove coals; 1,000 tons chestnut coal; 7,800 tons pea coal; 174,200 tons No. 1 buckwheat; 20,800 tons rice coal; 190,000 net tons bituminous mine run, 5,000 net tons fine washed blacksmith; 20,800 net tons screenings; 20,800 net tons prepared stoker coal and 1,458,400 net tons bituminous mine run. The specifications provide that prices are subject to readjustment in case existing rates for mine labor are changed.

The annual banquet of the Bituminous Coal Association of the Buffalo district took place in the neighboring village of Williams-ville on Feb. 28, with about 75 in attendance, including several from Pittsburgh, Cleveland and other coal centers. A. L. Stubbs, local agent of the J. P. Burton Coal Co., of Cleveland, was in charge of the program.

Directors of the Lehigh & Wilkes-Barre Coal Co. have declared a dividend of \$5 a share on the capital stock payable March 1, to stockholders of record Feb. 20.

The Steamship Fuel Corporation, of New York City, which also has offices in Philadelphia, Boston, Baltimore, Springfield and Norfolk, announces the opening of a sales office at 872-74-76 Ellicott Square, Buffalo, N. Y., in charge of J. Fred Morlock.

The Pittsburgh Terminal Coal Co. has opened an office in the Prudential Building, Buffalo, and placed it in charge of J. E. Doran, of Pittsburgh.

NORTH DAKOTA

State officials are directing forces fighting a fire of mysterious origin in a mine of the Haynes Coal Mining Co., at Haynes. Officials hope to keep the blaze from spreading to adjoining lignite mines owned by North Dakota and South Dakota. The two states have been asked to advance \$50,000 each to help extinguish the flames. The Haynes Mine was damaged last year by a fire set by a crazed miner.

OHIO

A fire at the mine of the North Hocking Coal Co., near Murray City, destroyed the tippie and much valuable machinery. Work will be stopped for some time and about 75 men are thrown out of employment.

A meeting of a number of locals of the United Mine Workers of Southern Ohio will be held soon, when steps will be taken to iron out a number of difficulties with the operators on the mining scale. A movement is on foot to have the miners waive payment for all dead work, which has been costing the operators about 50c. on the ton for all coal produced in the district.

Failure of the Rome Coal Co., of Columbus, to pay its delinquent premiums under the Ohio Compensation law caused action to be taken for a receiver in the local courts. Willis Liggett was named receiver in the action brought by Attorney General Crabbe of Ohio. The delinquent premiums amount to \$1,171.78.

William J. Hamilton, head of the W. J. Hamilton Coal & Coke Co., Columbus, has filed a petition in voluntary bankruptcy in the federal court at Columbus listing liabilities at \$281,079.95 and assets of \$126,753.48. Of the liabilities \$156,534.82 are unsecured and \$55,792.26 are secured. The assets consist of land in Morgan and Perry counties, underlaid with coal valued at \$13,238, accounts receivable of \$100,951.37; promissory notes of \$6,524.29; office furniture, \$4,137.26 and a small amount of cash. Mr. Hamilton has been in the jobbing business in Columbus for about 20 years.

The Majestic Coal Co., Marion, has been chartered with an authorized capital of 500 shares, no par value designated, to mine coal and deal in coal and coke. Incorporators are E. G. Fickell, R. B. Baldwin, Arthur S. Burket, E. L. Kaiser, and M. V. Kessler. Offices of the company are at 150 Center St.

Papers have been filed with the Secretary of State, authorizing the increase in capital stock of the Beluan Coal Co. from \$450,000 to \$650,000. C. A. McFadden is president and O. G. Beans, secretary of the company.

The accounting department of the Ft. Dearborn Coal Co. has been moved from Chicago to Cincinnati and will be under the direction of Lake Bobbitt. Sales offices of the company will continue in Chicago for the Western territory. The headquarters of the company will be moved to enlarged quarters on the eighth floor of the new Frederick H. Schmidt Co. Building.

The Hatfield-Reliance Coal Co., of Cincinnati, has been chartered with an authorized capital of \$10,000 to produce, buy, sell and deal in coal and building materials. Incorporators are: John G. Metcalf, J. T. Metcalf, F. J. Ed. Bramlage, John W. Stinborn and William J. Mulhivill.

OKLAHOMA

The Montezuma Creek Coal Co. has been incorporated at Okmulgee with a capital of \$50,000. The incorporators are Harlan Reed, H. D. Loyd and Ruth Barnett, all of Okmulgee.

A labor lien claim totalling \$23,299.10 has been filed at Henryetta by United Mine Workers union local No. 3061 in the case of W. H. Crume as trustee against the Southwestern Coal & Oil Co., of Okmulgee. The miners allege a prior claim over and above the First National Bank of Okmulgee, the petitioner in the receivership action. Harlan Reed, an official of the coal company, and W. T. Bowling are receivers.

The Black Diamond Coal Co., which recently began operating in the Garland district, shipped its first carload of coal early in February. It went to northeast Arkansas. There are approximately a dozen strip-pit enterprises now in operation.

PENNSYLVANIA

Wurley W. Gillett has resigned as purchasing agent of the Hillman Coal & Coke Co., of Pittsburgh, and has taken an interest and part of the management of Gellatly & Co., manufacturers' agents, Oliver Building, Pittsburgh.

George S. Baton, of Baton & Elliott, consulting mining engineers, Pittsburgh, has been placed by the Union Trust Co., of Pittsburgh, in charge of the operations taken over from the receivers of the American Coke Corporation a few months ago. The plants consist of American Nos. 1 and 2, at Linn and Martin respectively, both in Fayette County. No. 1 has 142 beehive ovens, but is nearly worked out, having only about 25 or 30 acres of available coal left. No. 2 has 240 beehive ovens and has

a large body of unworked coal still remaining. No move has yet been made to resume operations at either of these plants, which have been idle since last November.

The General Grievance Committee of the Hudson Coal Co. adopted a resolution March 1 protesting against the order of Governor Pinchot, and concurred in by Joseph Walsh, State Secretary of Mines, that "all mine inspectors shall work for a period of two months without compensation" and asking that "vacancies in three anthracite districts" now existing be filled, "so that proper care can be taken that life and limb shall be preserved about the anthracite mines." The resolution was accompanied by a letter to the Governor requesting reconsideration of his order and that action be taken along the line suggested.

A threatened strike of 800 employees at the Pine colliery of the Glen Alden Coal Co. was settled at a conference, March 4, between Rinaldo Cappellini, president No. 1 district, United Mine Workers of America; W. W. Inglis and S. B. Dimmick, president and general manager Glen Alden Coal Co. This controversy has been three years in process of settlement.

Earnings of the Bucyrus Co., of Milwaukee, during 1923 were \$25.50 per share on the common stock, which was the largest in the history of the company, according to President W. W. Coleman's letter to stockholders. The total earnings for the year after all deductions was \$1,299,932, as compared with \$746,301 in 1922 and \$1,010,985 in 1920, the best previous year. The company went into 1924 with a larger volume of orders on its books than it had at the opening of 1923.

The Carnegie Coal Co. with big holdings in Washington County, has filed with the recorder a mortgage of \$7,500,000, given to the Colonial Trust Co. of Pittsburgh, to secure the first mortgage 6 per cent serial gold coupon bonds issued by that firm.

The following coal companies were incorporated recently at the State Department at Harrisburg: W. G. Robertson Coal Co., Scranton, mining and preparing coal for the market; capital, \$50,000; treasurer, A. A. Sweetser, 1402 Price Street, Scranton. Incorporators: W. G. Robertson, A. A. Sweetser and J. Henry Jones, Scranton. Ampere Coal Co., Scranton, mining and preparing coal for the market; \$75,000; incorporators, A. A. Sweetser, 1402 Price Street, Scranton, treasurer; W. G. Robertson and J. Henry Jones, Scranton. The Homer Coal Co. Co., the Purity Coal Company and the Grazer Coal Mining Company have notified the State Department they have merged into the Cosgrove-Meehan Coal Co., of Pennsylvania, with a capital stock of \$315,000. J. E. Graham, Johnstown, is treasurer.

WEST VIRGINIA

Net earnings of the Clinchfield Coal Corporation in 1923, according to the annual report of the company, just out, were \$1,011,690.67 before fixed charges, the latter item amounting to \$107,881.70, leaving net income after fixed charges \$903,808.97. During the year \$246,104.35 was expended on improvements and developments. Output was 2,323,133 tons, an increase of 44,101 tons over 1922 and the largest yearly output in the history of the company. The cost of coal, including selling expenses, for the year averaged \$2.3979; the average price for the year, f.o.b. at the mines, for all coal was \$2.7549, and the coal earnings, before interest, dividends and federal taxes, were 35.7c. per ton.

A heavy fire loss was sustained by the Low Moore Co. when the large tippie at the No. 1 operation, at Kay Moor, was completely destroyed by fire, the loss amounting to \$125,000. This was one of the largest tipples on New River and among other equipment destroyed was the crushing plant conveyor and three storage bins in which there was fully one thousand tons of prepared coal for use in coke ovens. It was possible to save the incline leading to the mine only by tearing out a portion of it in order to block the spread of the fire. The power house was not damaged, being of stone construction. It will require several months to replace the tippie. It will be replaced however by a tippie even larger and of more modern design than the one destroyed. In the meantime a temporary tippie has been constructed so as to permit continuous mining of coal for use in the company ovens.

The Kenova-Lincoln Coal Corporation has been organized by Virginia and West Virginia capitalists for the purpose of developing coal lands in Wayne and Mingo

Counties. This company, with a capital stock of \$100,000, has purchased 500 acres of coal and will begin the development of the acreage acquired within a short time. Organization of the company has been perfected by the election of the following officers: W. R. White, Bristol, Va., president; E. A. Schubert, Roanoke, Va., vice-president; W. H. Shelby, Huntington, treasurer. The company will have its principal office at Kenova.

The Katherine mine of the Antler Coal Co., at Lumberport, has been sold to the Sitnek Coal Mining Co., together with 200 acres of Pittsburgh coal. The new purchasers include Louis Sitnek, of Philadelphia; Ralph L. Rankin, secretary and treasurer of the Sitnek Fuel Co.; H. H. Stagers and Edmund Cramp, of Fairmont. Mr. Sitnek will become the president of the Sitnek Coal Mining Co., for which a charter has been applied, this company to be capitalized at \$500,000 consisting of 5,000 shares of a par value of \$100. Fairmont people will be interested in the new company. The company now being organized contemplates the expenditure of about \$100,000 for additional equipment. The Antler Coal Co., of which Col. Thomas W. Arnette is the president, will continue to operate two other mines—one at Round Bottom, on the Connellsville division of the Baltimore & Ohio, and the other known as the Sue mine, on the Charleston Division of the Baltimore & Ohio.

Organization of the Spice Creek Land Co., in which McDowell County business men are interested, has been perfected by the election of the following officers: E. W. Cullen, president; S. J. Cooper, vice-president; L. J. Signiaco, secretary; Jno. M. Cook, treasurer. The stockholders, at their organization meeting, authorized the lease of coal land owned by the company.

WASHINGTON, D. C.

The Interior Department has classified more than one and one half million acres of land in Montana, Utah and Wyoming as coal land, and nearly 900,000 acres in California, Montana, Nevada, New Mexico, Utah and Washington as non-coal, of which 15,000 acres in New Mexico had been previously classified as coal lands. In Montana 1,700,000 acres previously withdrawn as coal lands were restored to entry.

CANADA

The annual meeting of shareholders of the Intercolonial Coal Mining Co., Ltd., was held at Montreal, March 5. The financial report showed results of operations to have been more satisfactory than for many years past. Operating profits, after allowing for depreciation and depletion, amounted to \$153,364, as compared with \$136,471 in 1922 before depreciation had been deducted. Net income on the common stock was equal to 29.27 per cent, as compared with 13.83 per cent in 1922. The balance sheet showed the company to be in a strong position with net working capital increased by more than \$40,000.

Another chapter has been written in the case of the Minudie Coal Co., which operated bituminous-coal mines at River Hebert for some years. For the past two years, the existence of this company has been sprinkled with strikes, labor disturbances, financial disaster, and now the property of the company has been seized and the assets auctioned for the benefit of creditors. The gross indebtedness is \$125,000. When the property was sold at auction the highest bid was \$10,500, which was accepted because of the need for ready money to pay claims of miners for wages. The purchaser was the provincial government, which has claims against the company totalling \$111,000 for workman's compensation, royalty, etc. For some time the government has been keeping the pits in repair, at a cost of about \$11,000.

According to the December report on the coal statistics of Canada just issued for the month of December the coal made available for consumption in the Dominion was 2,692,000 tons, a decrease of 12 per cent from November and 20 per cent from the three-year average of the month. For the whole year the coal made available for consumption showed an increase of 21 per cent. The output from Canada's mines for the month was 1,231,600 tons, a decrease of 17 per cent from November and 23 per cent from the three-year average for the month.

McGill Coal Co., Ltd., of Toronto, has been incorporated with an authorized capital of \$250,000. George H. Sedgewick, James Aitchison, John W. Pickup and others are the provisional directors.

New Equipment

Acid-Resisting Valve for Reciprocating Pumps

The Durabla Manufacturing Co., New York, has recently placed on the market a monel metal valve particularly suitable for reciprocating type mine pumps. The view of the valve shows a disk *A* arched so as to close upon an inner and outer valve seat. This construction makes possible a strong disk made from a very thin sheet of material. This latter feature is highly desirable because it prevents the tendency to chatter regardless of the position of the valve. The guard *B* is a protector to the spring and also limits the movement of the valve disk.

Aside from being acid-resisting, the material of the valve and its construction is such that it is suitable for use with many different kinds of liquids at various temperatures and pressures.

Monel Metal Valve

An acid-resisting valve specially suitable for use on reciprocating type mine pumps greatly reduces the idle time usually necessary for renewing worn or corroded parts.

Low-Freezing Dynamite

Tests were recently conducted at Hibbing and Virginia in northern Minnesota which prove that ordinary straight 40 per cent dynamite now being made by the du Pont Company on a low freezing formula was practically unaffected at a temperature of 35 deg. below zero. A continuous series of tests which had been made during the comparatively mild winter weather at those points when the temperature was at zero or a few degrees below, proved that the low freezing dynamite would detonate without difficulty. In the test made at 35 deg. below zero, it was shown that one cartridge would detonate another at a distance of one foot.

The development of this low-freezing dynamite is considered to be the greatest advance made in the explosive field since the invention of dynamite by Nobel. It makes possible the use of dynamite in road building and all kinds of open construction work under any temperature encountered in the United States.

This low-freezing dynamite created a sensation last year when it was used in some ditch blasting work in the

Northern states. The night before the ditch was shot, the explosives had been subjected to a temperature of 10 deg. below zero. The ground was frozen and covered with snow. The next day the holes were punched through the frozen ground, and the dynamite put down. It was shot by the propagation method where the detonation of one cartridge sets off the others. There was no difficulty whatever experienced. The dynamite showed the same qualities which it would show in the summertime.

Fountains for Wash Room

The Bradley Washfountain Co., of Milwaukee, Wis., is now manufacturing a washing fountain suitable for installation in mining company offices and wash houses.

Because of its circular shape, it easily accommodates a large number of people and at the same time gives them more available elbow room. The wash-room equipment and floor space is thereby materially reduced, as is also

Sanitary Type Wash Fountain

One inlet and one outlet control eliminates water wastage, and provides continuous flow of water which is always desirable for carrying away the dirt after it is loosened by the soap.

the time ordinarily required for washing. Each fountain has only one water inlet and one large open drain. This eliminates the continual nuisance of clogged waste pipes and leaky faucets. The spilling of water on the floors and walls is almost completely eliminated, thus materially reducing the cost of upkeep.

The fountains may also be provided with special fixtures, such as enameled trays for holding cake-soap and liquid soap containers.

Self-Contained Gathering Pump

The Diamond Machine Co., of Monongahela, Pa., has recently developed a new self-contained pumping unit. The power frame is cast integral with the motor sub-base and forms a compartment for the working parts and a reservoir for lubricating oil which is closed with a removeable cast iron cover. A bored crosshead guide, bolted to the power frame is extended to carry the water end.

The gears and eccentric are keyed to seamless steel sleeves, fitted with removable bronze bushings, and turn on stationary axles as separators extending through the frame. The gears are duplicates as well as the sleeves, bushings and axles. A small quantity of

oil in this compartment provides ample lubrication by the splash system to the gear teeth and all moving parts except the motor bearings. Brackets for truck axles are provided on the sub-base and are so placed to give the lowest possible height above the track.

The water end is exceptionally heavy and is furnished in acid-resisting metal or is cast iron bronze fitted. A removable cylinder liner held in place by two studs through the rear cylinder head, is regularly furnished in acid-resisting bronze. A special liner of extreme hardness, great durability and resistance to wear, can also be furnished. The cylinder is reversible end for end so that the suction and discharge openings can be placed on the side most convenient for piping. All studs are of acid-resisting steel.

Pump Motor and Gear Reduction Unit

This equipment is substantially built so as to require continuous operation at low maintenance cost. All parts are carefully protected against corrosion and dirt.

Fine Anthracite an Intruder

IN THE domestic field fine anthracite is an intruder. It has to force every inch of its way. Its use as an exclusive fuel demands special equipment. Consequently it has more reason than large coal to be kept up to the best standard that can be continuously and broadly maintained. The prejudices are against the fuel, and consequently it might pay perhaps to raise the standards for its preparation. We do not say that we know it would be advisable, only that it *might* be profitable to do so.

Innovators easily are discouraged and easily do they discourage others. For instance, an ex-treasurer of an anthracite company had a heater that would burn No. 1 buckwheat. He got a bad brand of that fuel, and he promptly concluded that pea was the fuel for him. Doubtless he could burn the finer coal satisfactorily, but he no longer attempts it. Had the buckwheat he got been cleaner he would have been burning that size yet. His neighbors are purchasing it and apparently find that the use of it pays.

Clearly then, one delivery of bad buckwheat, no matter whence it comes, can do immense injury to the whole business. It creates an unfavorable attitude to that size, no matter where produced. It hinders the public from equipping itself to burn fine anthracite. The injury wrought by one substandard delivery is incalculable. The honorable producer suffers with the dishonorable and suffers longer, for he is striving to live on in the business rather than to make a big stake and withdraw.

Localism of Consulting Engineers

MUCH care should be exercised in the choice of a consulting engineer. A man in a given locality is the best judge, as a rule, of a local property. He knows the market, the standing of the coal in public estimation, the value of coal lands, the prospects of trouble in operation, and if he is freed of favoritism and prejudice he can make a good report. Unfortunately, that is rarely the condition of his mind. He may steel himself to render a fair appraisal, but circumstances are likely to be against him.

Send him, however, to another field and he is prone to make other false judgments. He may go from a high-volatile to a low-volatile coal, and seeing the coal is of a somber hue and breaks up fine he overlooks its sterling qualities. He has been catering all his life to a market demanding lump coal, prejudiced against coal that does not glisten and that has few stokers to absorb the slack. Consequently he returns an unfavorable report.

Perhaps he finds that the coal is not of the bed which has attained a fair name in the past but is in one of lower quality. He forgets that the other bed

is worked out, that the market has become well content to accept the coal from the new bed, now that it has no competition. He exploits his one piece of geological knowledge but serves only to mislead his client.

It takes a broad knowledge to make a good consulting engineer, and some humility. If a certain coal is selling he must still that desire of his to say that by all the rules of the selling game it ought not to sell. It may be well if he should find the cost of mining and freight to be high to inquire whether that is acting as a deterrent to business; if it is low he will still do well to ask whether the market is satisfied to buy it. The coal may clinker on the grate. It may have a particularly strong rival in the marketing field. Selling coal is not all geology, as coal men know, but this fact is not always appreciated by geologically minded engineers from other regions than that being investigated.

So much for a producing region. The consulting engineer for a region not yet producing or only just beginning to produce needs still more to be a superman.

Every Man Has His Mental Twist

MOST of us are victims of mental habit and our employees are no more free from that twist of mind than others. It is a wise man who sums up correctly the natural bent of those whose services he is employing. Most non-technical mining men have the direction of human effort as their major qualification. To place their attention on anything else requires earnest and even painful mental effort, and most of them pursue the line of least resistance and avoid such cerebrations.

Many men would sooner wander around a mine than write a letter or cast up a line of figures to find out what their coal cost may be on any given day. Others there are who would write their letters and calculate their costs and distribute them before they would enter the mine to make an examination. They would find a hundred reasons to justify their action, and their reasoning would not be easily controverted.

Some men have an actual abhorrence of machinery. In earlier years they did not use it. To coddle a troublesome machine, to wrestle with the problems involved in making a pump run steadily are alien and displeasing jobs. They would sooner inquire why one man is a slow worker and why a certain miner loads dirty coal—two important matters, to be sure, and needing attention, but still, not sometimes as important as some mechanical matter which may keep many men or the whole mine idle. In fact a disinclination to busy himself with mechanical details has kept many a man from proving a good superintendent and has been the cause why many a mechanical device has not proved effective or efficient.

Foremen have learned by long experience that idle haulage men mean high cost of coal and presage

demotion. In consequence, they are little disposed to hold the transportation system standing for a while even if thereby they can keep a large number of day-wage men on a mechanical shovel from loafing on the company's time. As a result the shovel has failed to do its duty.

In fact every innovation has met with silent resistance from men whose thinking processes could not adapt themselves to it. Several years are often needed to fit the superintendent or the foreman to his new environment. He has to be compelled for a while to do violence to his inclinations. He has to overcome his subconscious tendency to do everything as if the old conditions still ruled, to argue all problems as if the old difficulties and not new ones had to be met.

The successful manager will sense this opposition, none the less because it is not vocal or obvious. If he hopes to make an important change in a subordinate's habit he will have to be a skillful advocate and follow his reasoning with pressure. That cannot be done at long range or without a knowledge of the idiosyncracies of the man in subordinate charge. Several visits to the mine are necessary and perhaps some changes in personnel.

It is quite easy usually when on the ground to find out if some primary duties are being neglected in favor of secondary duties that might be permitted to wait. Sometimes it is better not to try to teach "an old dog new tricks," but to rearrange matters so that the responsibility for new duties shall fall either on shoulders of men more progressive or of those whose habits fit more closely with the new need.

Our Shattered Faith in Water

ANYONE who has sprinkled wet coal on a fire knows that the water has little effect compared with that of the coal that goes with it. The glowing coals beneath the wet slack are not quenched, they are fed with new combustible.

We are losing faith in water as an immunizing agent in preventing explosions. Saturated air certainly has no appreciable effect in preventing an explosion so long as the dust is dry. By this is meant that to satisfy with water vapor the air entering a mine will in no way deter the extension of a dust explosion.

Saturated air and thorough sprinkling will assist in making the mine safe. It will certainly tend to keep down the dust, and it is likely that it will keep the fallen coal in roadways from degradation. Probably a mine kept saturated will have granular rather than decrepitated coal in the passageways. We do not know why some mines explode violently and others do not have explosions but it is possible that in some the coal tends in itself to comminute and in other mines it does not become fine except as a result of the crushing and grinding processes of traffic and travel. There are other reasons of course, as the Bureau of Mines has demonstrated, but this seems quite a probable reason why some dusts explode readily and others do not.

If coal under water or in saturated air is protected from deterioration it may be prevented thereby from becoming dangerous. Furthermore if some is ground and some is still granular the granules will cover the dust and make for protection. It has even been suggested that coarse coal may assist in smothering an explosion.

We might suggest that a layer of fresh fallen un-

broken coal may be a protection rather than a menace. That sounds and perhaps is a dangerous doctrine, but it may be worthy of consideration. The point arises: "Are our mines safer than they would be if we had less fallen coal in our roadways?" Do they not cover fine coal with granular and so work out an immunity from a violent explosion?

Dangerous as this question seems to be it must be faced. If we are going to build coaltight cars, if we are going to load our cars less heavily, will they increase or decrease immunity, and if they will increase it in some, will they increase it in those where the coal is self-decrepitatory or will they decrease it?

Truly, Dr. Wheeler is right when he says little is known about the coal-dust hazard. It is cheering that he says also in the addresses that we brief this week that perhaps 10 per cent of rock dust may help in this country even though 50 per cent has failed in some English mines. We hope he is not too optimistic in making this suggestion.

He needs, of course, to be careful of generalizations about the United States. It is less a unit than Great Britain. With lignite and low-volatile coal, with a relative dryness and wetness that Great Britain, we believe, cannot duplicate, we must be cautious in believing that his suggestion has a broad application to all sections of our country and must even be careful in assuming it is true in any of our bituminous coal mines.

Still his suggestion gives us all hope. We are sprinkling so much coal from the tops and sides of our cars that the suggestion that we use 50 per cent of rock dust is staggering unless we change our car loading and adopt everywhere cars suited to the rotary dump such as Great Britain so generally, if not so invariably, uses. His table of applications of rock dust and their results might be valuable in England but here they merely suggest what we could do if we would mend our ways at great expense, for coal transportation, repairs and equipment.

Give Your Shovels a Fair Trial

TOO many companies try out a new mechanical shovel in a mine without providing the conditions that alone will make the experiment successful. To put one under the charge of a foreman already harassed by a thousand operating problems is not likely to bring the results sought. The better plan is to give the new devices a mine of their own, properly, yes, even excessively staffed, and then concentrate all effort on the results. If regarded as somebody's side issue they will not succeed.

Let the man operating the mechanical-shovel mine or the section worked with such a machine realize that his reputation depends solely on his ability to get results with the new equipment. Provide a suitable mechanical engineer and proper equipment for repairs. See that adequate locomotive service is provided. Let the shovels have every aid that good judgment prescribes, especially conveyor service. See that there are no delays at the tippie. Afford always adequate power for operation. After the device has proved its value it is always possible to extend its use, but if sent into a mine to take its chances with opposition from some and with the languid interest of others, it will almost certainly fail. The mechanical shovel needs sympathetic treatment from its owners or its problems will not be solved.

Machine for Channeling Coal in a Strip Pit

Coal Stripper Uses Ice Harvesters' Method

Turns Longwall Cutting Machine on Edge "Sawing" 28-in. Seam Into Panels 12-Ft. Wide So That Pop Shots Make Less Screenings - Scheme Reduces Over-all Cost of Coal

BY DON M. SUTER
St. Louis, Mo.

THE coal strip-pit operator is taking a leaf from the ice harvesters' book. He is "sawing" up his coal into long panels, 12-ft. wide so that a few pop shots will loosen it in big lumps for easy and economical loading. This reduces labor and powder costs and saves time. It increases the value of the coal because the fuel comes cleaner and with less slack. It also improves strip-pit practice in a variety of other ways.

All this is directly creditable to the adaptability of a type of underground longwall coal cutter for open-cut mining. The machine, instead of lying in its normal horizontal position with its cutter bar extending outward, as for an undercut, is turned up on its edge with the cutter bar extending downward. Thus the machine performs the function of the ice harvester's cross-cut saw. The Leavell Coal Co., near Tulsa, Okla., is among the first to profit by this method.

MACHINE CUTTING REDUCES PRODUCTION COSTS

Most strip-pit men worry over their problems of loosening the coal. After the cover has been removed and the surface of the seam has been swept, the process of breaking up the coal is varied, and often is wasteful in cases where the coal is too thick and hard to be lifted by the loading shovel unaided. Usually many holes have to be drilled. The powder charge in these holes may be fairly heavy because the coal has only one loose end, namely, the upper surface of the seam. These relatively heavy shots necessarily shatter the coal and produce a large quantity of screenings and slack. Where the coal

can be wedged loose by the plug-and-feather method, the shattering effects of powder are avoided, but much time and labor are required to drill the holes and drive the wedges. The machine-cutting process as now practiced by the Leavell Coal Co., obviates these difficulties and reduces the production cost.

IS BIGGEST PRODUCER IN SOUTH WEST

The Leavell strip pit is one mile from the city limits of Tulsa, Okla. The company's holdings cover 600 acres of coal land, which is developed by stripping tracts 50 ft. wide and two miles long. The coal seam is 28 in. thick and furnishes an excellent grade of clean fuel, which is prepared in three forms, namely 6-in. lump, egg-and-nut mixed and slack. The annual output is about 110,000 tons. In 1922, the Leavell pit shipped more coal than any mine in the Southwest. In November, 1923, 10,200 tons were shipped.

The overburden is from 19 to 35 ft. thick, with varying quantities of blue and yellow shales, which must be shot to permit the stripping shovel to handle them. The drilling for these shots is done by water-well drills working from the surface. A steam shovel strips the coal. It is equipped with a 7-yd. dipper and an 80-ft. boom. The coal is loaded into three-ton cars with roller-bearing wheels, by a horizontal thrust coal loader, having a one-ton dipper and a pit width capacity of 65 ft.

Prior to last August, the coal was drilled with a hammer drill, operated by a belt-driven air compressor, and "shot off the solid." This method had a tendency

Machine Making Its Cut

The cutter bar extends vertically downward from the rear of the machine, channeling the coal as it works itself along the chain extending out at the right of the picture. Two men are required, an operator and a helper who shovels cuttings away from the channel. The chain causes the machine to move in a straight line, which is a great advantage, at the edge of the excavation.

to break up the lump coal, naturally reducing its market value.

Accordingly, in August, 1923, the company installed its vertical cutting or channeling Sullivan machine, and with it has obtained some interesting and valuable results.

This new coal cutter is a longwall machine, turned up on its side, and mounted on a steel shoe or skid. When moving from place to place, the cutter bar is locked in line with the body of the machine. When ready to cut, the locking pin is removed, the feed chain attached to the machine, and a vertical sumping cut is made, similar to the horizontal cut made by the ordinary longwall cutter in a longwall mine. When the bar stands vertically, or at right angles to the body, it is locked in place, and the machine is ready to cut its channel.

The lines to be cut are laid off lengthwise of the pit, and a hole is bored every 50 ft. ahead of the machine.

In these holes pins are inserted, to which the feed chain is secured. The machine pulls itself along the chain on its skid, making a straight cut the full depth of the seam. Two men, a runner and a helper, handle the cutter. The helper's chief duty is to shovel the cuttings away from the channel.

At the Leavell pit, which as already noted is 50 ft. wide, four channels each 150 ft. long are cut by the machine 12 ft. apart, and the machine handles the 600 ft. of cutting readily in an eight-hour shift. It is thus able to keep well ahead of the loading shovel.

Two holes are drilled in each 12-foot. block of coal, 3 to 4 ft. in from the free end. These are shot with 6 oz. of black powder each, the two holes being wired together. The longitudinal cuts provide two additional free faces, so that the light powder charge is sufficient to crack off the coal, without materially shattering the lump. As a result, the percentage of large coal has been increased from 12 to 15 per cent, and the cost of powder

The Leavell Pit, Near Tulsa, Where Cutting Machines Made Their Debut in Coal Stripping

After the cover is removed by the big shovel in the background, longwall cutters, operating on edge, "saw" the 28-in. seam

into panels 12 ft. wide so that light shooting loosens it in big lumps for the loader in the foreground. Operation is speedier.

the loader gets greater efficiency, and the coal is produced at lower cost than it was under former methods.

Strip Pit Coal Cutter Getting Ready for Action

It is a longwall cutter turned on edge and mounted on a shoe. The chain, here shown unattached, is hooked to a pin 50 ft. ahead of the machine. The cutter bar, long enough to penetrate the seam, sumps in until it is vertical to the frame. Then the machine cuts along the chain.

per ton has been cut in half. One keg of powder now loosens 200 tons of coal, instead of 100 tons, which was all that could be obtained without channeling.

LESS THAN 20 PER CENT IS SCREENINGS

The tippie at the Leavell pit is equipped with shaker screens and loading booms. Their loading record in a recent month showed lump 65 per cent, egg-and-nut mixture 15.5 per cent, and screenings, 19.5 per cent.

A smooth, unbroken coal face is left by the mining machine instead of a jagged broken face. For this reason, it is possible to lay the loading track close to the cut with no danger of its crumbling under the weight of the cars and locomotive. Before the machine was used, a much wider shoulder had to be left for support. The clean, solid face also enables the loading shovel to do a better job, and it is estimated that the capacity of the shovel has been increased 25 per cent by this feature and by the larger coal obtained. The solid face also assists the stripping shovel on its next trip, and the cut is thereby carried as close to the overburden as possible. This reduces the quantity of coal lost by deposits of overburden from the shovel.

The cuttings from the machine are coarse and are graded as screenings and not as slack. With contemplated improvements in firing the big shovel, these cuttings may be substituted for lump, thus making some 300 tons more of large coal available for the market monthly.

The mining machine is operated on 440 volts alternating current, which is stepped down from the 11,000-volt supply of the Public Service Co., of Oklahoma, to 2,300 volts by transformers at the tippie, and carried along the pit side to secondary transformers which are moved as the pit progresses. Rubber-covered cable carries the 440-volt current from the pit bank to the machine.

The Leavell Coal Co. is obtaining from its channeling machine all the advantages which accrue from the use of mining machines underground, namely, a more marketable product at lower cost for powder and labor, a better physical condition of the property, and a more complete recovery of the coal.

Even Coal and Non-Siliceous Dusts Harmful to Health*

Any Dust, Especially if Not Soluble in Water Will Clog the Lungs—Miner's Asthma a Form of Consumption

BY D. HARRINGTON,
U. S. Bureau of Mines, Denver, Colo.

THE following impressions regarding dusts in mines are the result of general observations in coal and metal mines during nearly 25 years, about seven years of which were devoted to a more or less intense study of dust. Though many of the views expressed are at variance with the ideas of eminent authorities, it is felt that there is at hand sufficient supporting evidence, though it will not be given here.

Any dust insoluble in the fluids of the respiratory passages, and in sufficiently finely divided form to float in the air and be breathed by underground workers, will ultimately be harmful to health if the dust is in the air in large quantities and is breathed by workers for long periods of time. This applies to insoluble non-mineral as well as mineral dusts or mixtures of them and includes coal dust or mixtures of coal and other dusts.

The lungs appear to be affected by dusts largely as would a sponge if its open spaces were gradually filled with fine sand; ultimately there would be practically no expansion or contraction possible and the ability of the sponge to take up or release water or similar material would be destroyed. As the lung cells are gradually being filled with dust, the lungs are correspondingly prevented from performing their usual functions, vitality is reduced and the body becomes a prey for disease germs, especially those of tuberculosis.

INFINITESIMAL PARTICLES SOLUBLE IN WATER

It appears that the dusts which lodge in the lungs usually are less than 10 microns in size, and are insoluble in the fluids of the lungs. It seems probable that much of the extremely fine, ordinarily insoluble, dust (that below 0.00001 in., or $\frac{1}{4}$ micron) is soluble in the lung fluids; at any rate, it has been proved that very small particles of such extremely insoluble matter as flint and chert (free silica) are definitely soluble in distilled water. It now seems probable that the dust dangerous to lungs is between 10 microns and 0.1 micron in size.

Silica dust, whether free or combined, is not always in equally dangerous form nor are all kinds of free silica (quartz, chert, flint, etc.) always equally dangerous, nor do particles of free or crystalline quartz always have sharp cutting edges, though when the sharp needlelike or knife-like edges are found, they constitute probably the most dangerous kind of dusts that can be breathed. Insoluble mineral dusts without presence of silica or mixtures of quartz or other siliceous dust, with other more or less insoluble dusts such as calcite, alumina, hematite, etc., are likely to be harmful if in finely divided state and present in large numbers in air breathed by underground workers.

Coal miners working at very dusty occupations or in moderately dusty but poorly ventilated places get a lung involvement, frequently within a few years, called

*Paper entitled "Dust and the Health of Miners," presented at the meeting of the Industrial Relations Committee, American Institute of Mining and Metallurgical Engineers, at its February session.

miners' asthma, which is generally miners' consumption, having essentially the same symptoms and ultimate effect as phthisis or silicosis. Where lung involvement does not occur, coal miners in fairly dusty occupations or in places with poor air circulation and moderate dust content of air frequently are afflicted with bronchitis, though the disease does not become apparent for many years.

Breathing of coal-dust laden air does not immunize or even partly protect a worker from being affected by miners' consumption when subsequently working in dusty metal mines; nor does work alternately in air laden with coal dust and with rock dust prevent harmful lung or bronchial involvement, and a worker with lung involvement from metal-mine air cannot expect relief by subsequently working in dusty or poorly ventilated places in coal mines.

The coal-mine occupations most likely to produce a dusty condition harmful to health are undercutting of coal or of material under the coal by chain machines, or the mining and shoveling of long-standing dry pillars, or working in places with little or no circulating air (especially when shoveling fine dry coal) or where frequent heavy blasts are made during the working shift.

OVER-EXERTION INCREASES DUST INHALATION

Contract workers in both coal and metal mines are more likely than others to be afflicted by dust diseases because of their failure to take time or to use available methods or appliances to protect themselves, and the over-exertion of contract workers causes increased rate and depth of breathing of dust-laden air, thus hastening the accumulation of dust in the respiratory passages.

When the air temperatures are above 80 deg. F., the humidity is over 90 per cent and the air is stagnant, the effects are intensified; and in mines with poor air circulation at working faces or where blasting is done during shift, poisonous carbon monoxide from explosive fumes hangs in the air and adds to dust danger by lowering the worker's vitality.

Some individuals are better able to resist the ill effects of breathing dusty air than others; and men of some nationalities seem less able than others to resist lung trouble from dust; the Irish and Finns apparently having minimum resistance to mine dust.

The logical remedy for the dust hazard in mines is prevention of the formation of dust, but that is not always possible and the most efficient and practicable method of protecting under-ground workers from dust is the circulation of continuous currents of pure air through and past points where workmen are found in mines. It is entirely probable that the reason why the dust in coal mines is less prejudicial to health than the dust in metal mines is due chiefly to the fact that the working places in coal mines are generally much better ventilated than those in metal mines.

Dust prevention in coal mines may be aided by: (a) using water sprays at the cutting chain on undercutting machines; (b) sprinkling the broken coal at the face with water while loading or after the car has been loaded, or both; (c) sprinkling the region of the working face before and after blasting; also at other times during the working shift; (d) sprinkling the roadways at least once or twice a week, washing down the ribs and timbers, as well as thoroughly wetting the floor; and if the roof material will permit, also washing down the roof, and timber caps near roof; (e) thoroughly spraying loaded coal cars at auxiliary partings, unless

they are sprinkled at the face, before they go into the main haulage roads, which usually have air currents of sufficiently high velocity to remove any fine dry dust from the tops of loaded cars; (f) eliminating blasting while the shift is in the mine. Blasting during shifts is dangerous to life on account of possible explosion or other accident; and dangerous to health because of the noxious gases that explosives produce, and because clouds of fine dust are thrown into the air to be breathed by the mine workers. Blasting during shifts is unnecessary, is an out-of-date practice and should be absolutely prohibited.

ROCK DUSTING NOT PREJUDICIAL TO HEALTH

The use of pulverized-rock dust in coal mines to prevent explosions is justified because the danger to life from explosions is infinitely greater than that from the breathing of dust. Moreover, dust is dangerous to health only when suspended in the air. The rock dust used to prevent explosions is not thus suspended and therefore cannot be breathed by workers. It is rather placed on the floor and ribs and in barriers. The relatively small quantity of rock dust thrown into the air during working periods should not be particularly dangerous to health, especially if the rock dust is selected so as to have minimum potential harmfulness.

Some authorities propose the introduction of coal dust into the air of metal mines as a possible preventive of miners' consumption. Even if this dust could be thrown into the air and kept there (a very difficult undertaking) it would introduce the explosion hazard into metal mines and, worst of all, would intensify the existing dust hazard rather than in any way alleviate it.

The usual types of respirators on the market do not prevent the breathing of the very small (hence most dangerous) dust particles, but, if workers could be prevailed upon to use them, the catching of the larger particles would help to hold some of the small ones; and the nasal and other passages thus relieved of catching the large particles would be more effective in catching the small. However, it seems impracticable to get respirators used at all consistently by workers.

All mining employees should be given physical examination at least once annually. To get definite data as to lung condition, X-ray photographs should be taken and interpreted by an expert on pneumoconiosis, otherwise dust involvement of lungs may escape notice, especially in coal mines, for several years.

Though coal dust is responsible for at least two-thirds of the loss of life in the mine explosions of the United States, it is entirely probable that a much greater number of men who have worked in our coal mines die annually of bronchitis, pneumonia, miners' asthma or other diseases caused directly or indirectly from coal dust, than die from mine explosions. It is well known that more men die annually from metal-mine dust than are killed in dust explosions in coal mines. Moreover, the economic loss from men partially disabled by different stages of miners' consumption in and around both coal and metal mines (though around coal mines the cause of the partial disability either is not named or is styled miners' asthma, etc.) certainly is not less than many millions of dollars per year in loss of output alone; and the misery caused the victims and their families cannot be estimated.

Hence dust is the scourge of the mine and the miner, and every feasible method of preventing its formation or of eliminating it should be consistently provided.

Shanktown Explosion Evidences Need of Greater Regard for Safety at Mines

Five Precautions Which Should Have Been Observed—Condition of Machine Which Inspectors Said Caused Explosion—Miller Seam Has Shown Recently Many Indications of Unsafe Conditions

TESTIMONY at the inquest into the explosion at the Lancashire mine of the Lancashire Coal Co. (a subsidiary of the Barnes & Tucker Coal Co.), at Shanktown, Pa., was to the effect that many precautions which should have been taken were disregarded. According to the evidence, trolley locomotives were operating in the return airways in violation of Art. 11, Sec. 6, Rule 77, of the State Mining Law of Pennsylvania; an arc-welding machine was used in the return air, which was known to contain at times dangerous quantities of explosive gas; cutting-machine cables not provided with closed-type switches were connected openly to trolley wires by means of "hook" connections;

slope and was developed by four main entries. The mine was ventilated by a reversible fan which ran as an exhaust, drawing 75,000 cu.ft. of air per minute against a water gage of 2.5 in. That section of the mine which gives off gas is shown in Fig. 2.

ELECTRIC WELDER WAS USED INADVISABLY

Fireboss Joe Adams testified that he found gas at times in all places he inspected on his rounds, and that gas was generated in dangerous quantities in all the live development entries. He admitted that a hoist, a pump and an electric welder, the first two machines not complying with the closed-type standards of the U. S. Bureau of Mines and the last an exceedingly dangerous appurtenance if used in places generating gas, were used in the Eighth Right section, where the explosion originated.

Examination of Mine Electrician Wolf disclosed that weekly inspections of cutting machines to detect defective connections, etc., were not made. Only when a machine broke down did it receive this attention. It was said that the rheostat cover on the particular cutting machine that the mine inspectors declared caused the explosion, and that was working in No. 1 Butt airway off the Eighth Right headings, had been punctured. In case of a short in the machine, the power circuit could not be broken through the controller without letting the customary arc of breaking project into the atmosphere. Neither fuses on cutting machines nor switches on cables, enclosed in explosion-proof casings, were used as required by the mining law.

It was stated at the inquest that though the rheostat cover is arranged for fastening with twenty-two bolts, only twelve were in place when the cutting machine was examined.

State Inspector T. J. Lewis, of the Twelfth Bituminous District, reported the finding of the investigation commission. It found explosive gas at the faces of the main slope entries but no manifestations that this was the source of the explosion. In the Seventh Left flat headings and in the room headings off the former and in some rooms also explosive gas was discovered.

An accumulation of gas was found in the Eighth Right flat headings. As shown in Fig. 2 the most advanced face is that of the haulageway, which is 223 ft. beyond the last crosscut. To avoid working the face to the dip the airway was being driven outby on the rise by a pocket from the last crosscut. Ventilation was maintained in this pocket by a canvas as indicated.

Fig. 1—Fan Came Through Explosion with Little Injury

Contrary to early reports little damage was done to the fan house by the force of the Lancashire mine explosion. A few leaks which developed in the roof were quickly stopped by tucking and covering with canvas.

no attempt was made to keep cutting machines safe by careful maintenance and weekly inspections, as required in Art. 11, Rules 1 and 70; miners without safety lamps in certain instances were allowed to fire shots, though a shotfirer was employed; such firing being forbidden under Art. 4, Sec. 14.

It must be conceded that the Lancashire mine No. 18 had not been long in the hands of the Lancashire Coal Co. Up to Dec. 15, just thirty-nine days before the explosion, it had been owned by the Glenside Coal Co. It was operated in the Lower Kittanning bed, sometimes termed the "B" or Miller seam. It was opened by a

Headpiece shows how slope mouth was not injured in any way. When the explosion occurred the hoistman was in the act of dropping down a trip of empties. All he saw was a big blow of smoke, which spent itself immediately on reaching the outside. Though stoppings were demolished, mine cars and track were little damaged. Rescue crews pushed mine cars of supplies ahead of them, in most cases without difficulty, as the roof did not fall as a result of the blast.

NOTE—Mine inspector's report on this disaster was printed in *Coal Age*, Feb. 21, p. 285.

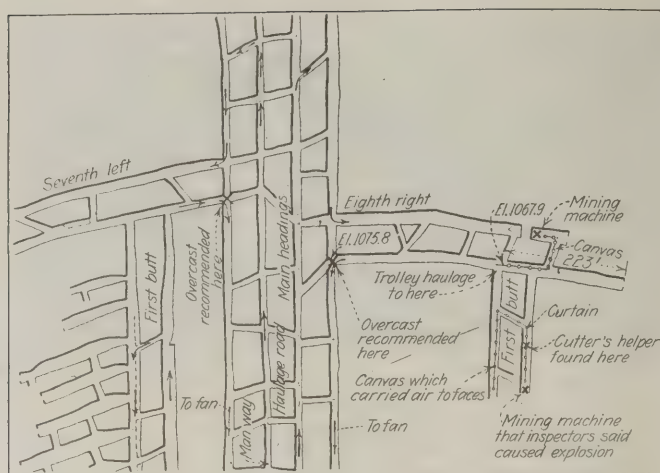

Fig. 2—Gaseous Section of Lancashire No. 18 Mine

Comment at the inquest favored the idea that, had the faces of the Eighth Right flat headings and those of its First Butt been driven in the ordinary manner, had the machines been duly inspected and had tests been made for explosive gas by the machine men, the explosion would not have occurred. With the entries as shown, too much reliance is placed on the efficiency with which the canvas would compel the air to sweep across the faces. Without overcasts, splits of intake air could not be made to reach the main cross-headings. Trolley wire, as will be seen, was strung in return air.

A mining machine was found in this place. There were no indications to show that the explosion had originated here.

At the face of the airway of No. 1 butt entry off Eighth Right flat headings, the commission found evidence of intense heat and much force developed outby. There was an accumulation of explosive gas at this point. Ventilation was maintained at the two faces of No. 1 butt headings by canvas strung from face to face through the first crosscut. At the face of the airway was a closed-type cutting machine which had completed a cut and apparently was being loaded onto its truck when the explosion took place.

A careful examination of this cutting machine showed that the rheostat was defective. Arcing apparently caused intense heat inside the cover. The heat was so intense that it had burned out the gasket between the frame of the machine and the cover, and also charred the lining of the latter. The rheostat, consequently, had ceased to be explosion-proof. The second point on the rheostat was burned off completely, and the first point was loose, whereas the third and fourth points were solid. Arcing in the rheostat without proper insulation was such that the whole machine became charged and could cause arcing at all points of ground.

ARCING, GAS AND COAL DUST MAY HAVE BEEN CAUSE

Such arcing, the generation of gas and the suspension of coal dust in the air may have combined to cause the explosion. A door on the return of the Eighth Right headings was blown out to the left rib of the nearest main heading, suggesting that the force of the explosion moved away from this particular place. Coked coal was seen on the inby side of the timbers, leading the inspectors to declare that the explosion moved outby. The machine cutter's helper was found about 70 ft. from the machine. It is believed that he was on his way to disconnect the cutting machine cable from the trolley on the Eighth Right, following the development of arcing in the cutting machine. Unfortunately, the explosion occurred before he could do this.

Reforms are much needed in the mines which are

working the Miller seam in Indiana County and the north of Cambria County, if the series of explosions extending over the last few years is to be broken.

In March of 1916 gas was ignited in the Robindale mine by an open light, eight men being killed. In May of 1920 an explosion of gas set off by an open light killed two men in the Lancashire No. 18 mine. Open lights ignited gas in Watkins No. 3 mine in June of 1921, killing two men who preceded a man trip into the mine; if it had occurred fifteen minutes later, this blast would have killed many men. At the Dilltown mine in April of 1922, four men were killed when a room hoist ignited gas. This hoist was located in a heading in advance of the intake air. The worst explosion of all took place in the Spangler shaft in November of 1922, when seventy-seven men were killed, a body of gas being ignited by an open light.

These six explosions together caused the death of 129 miners. The death toll might have been much greater had the explosions occurred when more men were at work. When workings in the Miller seam advance such great distances as to be covered by a thick overburden and gas is likely to be released in dangerous quantities, such workings become gaseous and call for compliance with those clauses of the mine law of the state that apply to gaseous mines.

Self-Rescuer From Carbon Monoxide Gas

Approval of a new type of safety device, a "self-rescuer," designed as a means of escape for persons accidentally caught in mine or other atmospheres containing carbon monoxide, has been given by the U. S. Bureau of Mines. This approval has been given to the Self-Rescuer, manufactured by the Mine Safety Appliances Co., of Pittsburgh, Pa., under the provisions of Schedule 14-A of the Bureau of Mines, which outlines the procedure for establishing a list of permissible gas masks.

The self-rescuer consists of a pocket size canister with mouthpiece directly attached, filled with granular fused calcium chloride and granular hoolamite (mixture of special copper oxide and manganese dioxide) which causes carbon monoxide in air to unite with the oxygen at ordinary temperatures forming harmless carbon dioxide. Cotton filters for removing smoke are also included in the canister. The self-rescuer and a nose clip for closing the nostrils are enclosed in a hermetically sealed brass case to prevent deterioration until used. The weight complete is about 1 lb. 5 oz. The small size permits carrying in the pocket or on the belt, for the latter purpose a metal belt loop being attached to the case.

Carbon monoxide self-rescuers may enable miners to escape from atmospheres containing carbon monoxide in mines following fires or explosions. They may also safeguard workers in industries above ground where carbon monoxide may be encountered, such as around blast furnaces and metallurgical operations, or in the chemical industries.

The self-rescuer is approved only for carbon monoxide. The Bureau of Mines does not recommend its use as a substitute for carbon monoxide gas masks, having large canisters designed to protect persons who are called upon voluntarily to meet carbon monoxide in the course of their work. The approval rather is limited to self-rescue by persons who may be accidentally caught by carbon monoxide.

By Tumbling the Reject and Air Cleaning Smalls, Indistinguishable Bone Is Freed of Ash

Refuse from the Picking Table After Being Rolled Around Loses Its Coal Content Which Is Crushed in the Process—This Coal Is Then Winnowed on an Air Table

BY RAY W. ARMS
Chicago, Ill.

DIFFICULTIES which would have foiled earlier engineers who depended on water jigs are being met by dry-cleaning methods. Finely crushed coal was jigged inefficiently and with difficulty, and much coal was washed away in the streams. Now, the coal in the rejects of picking tables can be crushed and removed and then cleaned by air, giving an excellent slack product which will not freeze in the car or arrive at the market with excessive water. Furthermore, freight no longer has to be paid on water and rubbish that cannot be burned.

The dry-cleaning plant built for the Wyoming Coal Co. at Wyco, W. Va., is located on the Virginian R.R., four miles from Mullens, W. Va. The No. 3 Pocahontas seam at this point contains a middle band several inches thick which is high in ash, and grades gradually and with no distinct line of separation into the usual low ash and high quality coal characteristic of the No. 3 Pocahontas bed. The coal in the outer edges of this bone band resembles so closely the best coal that it is quite impossible to remove in the mine anything but rock and a small quantity of the heaviest of this bone.

The coal, after being brought to the surface, is passed over a 1½-in. screen, the lump being hand-sorted over picking tables to remove as much of the bone coal as possible. After picking, the lump and slack are usually reassembled in the form of picked run-of-mine, as it is that size of coal which is marketed from this mine, and in fact, from a large part of the territory tributary to the Virginia R.R.

It soon became evident however that so much of the ash of the resultant run-of-mine coal was due to the slack, which could not be hand-picked that it was necessary to provide some means of mechanical separation.

W. P. Tams, president of the Wyoming Coal Co., personally conducted tests on various cleaning devices and finally determined that the best results could be obtained by installing a Bradford breaker in which the larger lumps of hand-picked bone could be shelled from the adhering coal, a pneumatic cleaning plant being added to clean the slack as well as to treat the fine coal obtained from the Bradford breaker. This cleaning plant was expected to remove all rock and those poorer grades of bone coal which were tending to keep the ash in the slack above the desired figure.

The plant, to accomplish this purpose, was designed and built by the Roberts and Schaefer Co., using a

Bradford breaker, elevators, conveyors, Hum-Mer screens, Universal rescreens, American pneumatic separators and a B. F. Sturtevant Co. dust-collecting system. The plant is constructed of timber and built adjacent to the tippie to which it delivers its cleaned product.

The first operation is that of breaking down the big lumps of bone coal in the Bradford breaker. The fine coal from this goes to the cleaning plant and the rejected material directly to a rock bin. The slack from the tippie together with this fine coal go direct to the foot of a bucket elevator capable of handling 175 tons per hour which raises them to the top of the dry-cleaner building whence they go through the succeeding operations by gravity.

A cross conveyor takes the coal from the elevator and distributes it to the top of a tandem series of four Hum-Mer screens, each of which drops the undersize to a pocket and delivers its oversize directly to the succeeding screen. The openings in these screens are of a size to divide the coal into the proper proportions and the proper sizes for the pneumatic separators. The undersize from the first of these screens is delivered to a second set of four screens which separates the fine coal into the sizes to be tabled.

DOESN'T TREAT SLACK UNDER ½ IN. DIAMETER

The finest of these screens is ½ in., the undersize of which is bypassed without further treatment to the slack coal. All screened products except these fines are run into five hoppers, each of 4-ton capacity, feeding the pneumatic tables. Attached to the bottoms of the bins are fine Universal rescreens which serve further to screen the products and remove the fine breakage occurring in the bins. These screens not only improve the operation of the table but reduce the dust which would otherwise be blown about on the table floor.

The re-screens feed to the five pneumatic separators which grade the coal in a discharge line varying from the heaviest refuse at one end to the best coal at the other. This line is divided into finished refuse (which is discarded) cleaned coal, and middlings, which are either to be returned to the foot of the elevator for retreatment in the plant, or used as a separate product under boilers or sold together with a part of the good coal as an inferior product.

The finished products are collected on a single, two-compartment, gathering conveyor which on one strand takes the cleaned coal to the tippie and the middlings to the elevators and on the other strand delivers the

NOTE—Illustration in headpiece shows Wyco dry-cleaning plant.

Another View of Dry Cleaning Plant with Tippie

In this plant the refuse from the picking table is broken in a revolving breaker and the fine coal removed. With the slack from the mine, the coal is sized and cleaned on air tables. The middlings product of these tables can be used under the boilers or again sent back through the process.

refuse to a bin and the middlings, if desired, to a separate bin.

To control the dust about the plant, care was taken

to keep the fine coal at all times under cover so that dust could not escape. With this end in view all conveyors, chutes and elevator were covered. Over the tables, where air tends to keep the dust in circulation, are placed dust hoods with such suction provided that all the air is removed from the covered area, a surplus being afforded to insure that the hoods will remove all dust. The covered area varies from about 50 per cent of the table surface to about 90 per cent, depending on the fineness of the coal and its tendency to produce dust. To prevent dust clouds from boiling up during screening, suction is provided on all hoppers leading from the screens. All the dust-laden air from these various sources goes through a fan and to a cyclone collector which removes the dust and delivers it to a covered screw conveyor which returns it to the slack.

The Wyco plant started operations Feb. 1 and has been running continuously ever since. It is too early to state what the actual results of the operation will be as the organization and training of the operating crew and the adjustments always incident to the starting up of a new plant so far have occupied the time of those in charge. From the few days of operation, however, it is apparent that refuse and bone are being removed from the coal with a minimum of expense.

The Miner's Torch

Making the Smoke Problem Our Problem

EVERYONE connected with the coal industry should be interested in Technical Paper No. 273, Subject: "Smoke Abatement." This paper has just come from the press and copies can be obtained from the U. S. Bureau of Mines, Washington, D. C.

During the war while there was a shortage of coal and an ever-growing demand for more and more production, most city smoke abatement ordinances were allowed to become ineffective, but now with a plentiful supply of coal assured there seems to be a growing demand for the enforcement of such ordinances.

Mr. Coal Operator, your city friends are liable to ask you embarrassing questions after they read some of the proposed smoke ordinances or listen to speakers who are working up a demand for such edicts. The paper referred to will give you the answer to most of the questions that will be put to you and instead of being on the defensive you may pose as an authority on the subject.

If the soft-coal men do not wake up it will only be a matter of a few years before coke, gas, or some other substitute will take the place of the soft coal now being used for domestic purposes. Although smoke from residences furnishes only about 10 per cent of the total smoke of the cities, such smoke is particularly destructive in its effects on property and vegetation and there is a growing conviction among physicians that it affects seriously persons suffering with acute lung diseases and possibly is one of the most common causes of cancer.

There may be chance for argument in discussing the effect of smoke on health because this is as yet largely a matter of opinion, but there is no chance for argument when committees appointed by city governments submit figures showing the additional cost to the aver-

age citizen for laundry bills, paint bills, etc., because of smoke-polluted air.

Of course, if we are to believe all the reports coming from the Ford engineers it will only be a few years at most until all soft coal will be turned to low-temperature coke and the smoke problem will be solved, but the paper under discussion does not mention the work of the Ford engineers and simply states "During the past 10 years increasing attention has been given to the possibility of low-temperature carbonization."

Approximately one-half of the paper deals with the domestic smoke problem and the information which it contains should be in the hands of everyone who burns coal for domestic purposes. If the producer of coal will pass such information on to the consumers he will render a service that must have far-reaching results. For example we learn that by simply changing the method of firing and without the expenditure of a penny for equipment the density of the smoke from an ordinary hot air furnace can be reduced from 11 to 4 per cent. The same thing is almost true of grate fires and kitchen-stove fires. I venture to say that half of the coal men who read this will question this statement at first sight so let me hasten to say that this is honest-to-goodness information and not propaganda.

One of the unfortunate conditions surrounding the coal industry is the lack of a point of contact between the producer and the consumer. The product that the consumer obtains is far from attractive in appearance and when he comes to pay for it he sees red instead of black. He knows nothing of the problems of the man who has his money invested in coal mines, nor of the men whose sustenance is dependent on their labor in the mines. If his memory is good he recalls "Coal Barons" and "Reds" but beyond that all is a blank. Taking such facts into consideration, would it not be better for the coal producer to take the initiative in assisting the general public with its smoke problem rather than to wait until the daily papers start the campaign with scary headlines something after this manner: "Soft coal smoke doubles our laundry bills and destroys our shade trees"?

Dr. Wheeler Explains That Wet Coal Dust Is Still Coal Dust And Liable to Explode

Haig Pit*

©Keystone View Co.

BY A. F. BROSKY

Assistant Editor, *Coal Age*

Only One Sure Cure Exists and That Is Fine Rock Dust, Not Only in Barriers, Though That Is Well, but Also Spread on Sides and Floor of Passageways

ROCK dusting—or “stone dusting” as the English mining engineers term the mixing of limestone or shale with coal dust to check the propagation of an explosion of the latter—seems likely to be adopted as a general practice in the United States. The interest created in this work following the recent visit abroad of George S. Rice, of the U. S. Bureau of Mines, and others is being intensified by a return visit to this country of Dr. R. V. Wheeler, director of the Mines Department Experimental Station at Eskmeals, and Henry Walker, deputy inspector of mines, both of Great Britain.

Arriving in New York City too late for the 129th meeting of the American Institute of Mining and Metallurgical Engineers, they made their first appearance in Pittsburgh, where the coal-mining activity of this country naturally centers. At a series of meetings the conferences in the Pittsburgh station of the U. S. Bureau of Mines, and in two lectures at the Carnegie Institute of Technology, Dr. Wheeler spoke of the factors which enter into gas and coal-dust explosions, placing greatest emphasis on the prevention of the latter by rock dusting; in fact he was obliged to do so because of the astonishing interest taken by men who attended these gatherings. Time and again his audience would revert to rock-dusting, revealing the thoughts which were uppermost in their minds. Can we and shall we dilute the content of combustible material of the dust which gathers in our underground workings? No doubt we shall.

DINNER IN ATHLETIC ASSOCIATION CLUBHOUSE

The English visitors were welcomed to the smoky city by a dinner in the clubhouse of the Pittsburgh Athletic Association. Men from the Bureau of Mines, representatives of coal companies, technical educationalists and engineers made up the dinner party of thirty-seven, which was limited in number to make the get-together informal. The after-dinner talk resolved into a quizzing of Dr. Wheeler and Mr. Walker who in turn asked questions of our own engineers. Inspection, regulation and practices as applied to the elimination of hazards in the mines of both countries were the topics

of discussion; rock-dusting was a subject much to the fore. Dr. Wheeler advocated without qualification the use of rock dust as the means best suited to prevent dust explosions, declaring that they will occur even after all other precautions have been taken. That rock-dusting does not remove the need for continuous effort in diminishing the hazards due to ventilation, electricity and machines, was another high mark in his speech.

No doubt the readers of *Coal Age* who did not have the opportunity of hearing Dr. Wheeler in Pittsburgh last week are eager, as were the 200 men who did, to learn more about explosions and how they may be made less hazardous by rock-dusting and other means. Lack of space limits this report to an account of Dr. Wheeler's two lectures and the discussions which followed in the “union room” of the Carnegie Institute of Technology in the evenings of March 5 and 6. What was said along similar lines at a joint meeting of the civil engineering section of the Engineers' Society of western Pennsylvania, the Pittsburgh section of the American Institute of Mining and Metallurgical Engineers and the Coal Mining Institute of America on the evening of March 4, as well as all that transpired in the assembly room of the Bureau's Pittsburgh station during an all-day mine safety conference will be told in next week's issue.

FIREDAAMP EXPLOSIONS SLOWER THAN COAL DUST

In his first lecture Dr. Wheeler dealt with the causes and physical characteristics of explosions in coal mines. Though these explosions account for only a small percentage of the fatal accidents that occur in coal mining, most of the deaths being due to falls of roof, they serve to make imminent an even more serious disaster. Much patient study has been devoted therefore, to the character of firedamp and coal-dust explosions, with a view to reducing, by the adoption of preventive measures, the likelihood of their occurrence.

Firedamp explosions, as compared to those caused by ignition of coal dust, are comparatively easy to study. The speed of propagation of a flame of firedamp and air is comparatively slow. Dr. Wheeler showed by curves on a lantern slide that the most rapid flame under conditions of “uniform movement” originates from a mixture of $9\frac{1}{2}$ to $10\frac{1}{2}$ per cent of methane with air.

When this mixture is ignited the flame moves with a speed of 90 cm. (35.4 in.) per second; the speed of an 8-per cent mixture is 70 cm. (27.6 in.) per second, and

*At this pit, which forms part of the Whitehaven Collieries, Cumberland, England, a serious explosion occurred Sept. 5, 1922. The Chief Inspector of Mines reported that it originated from the flame of a shot and that the evidence of coked dust showed that coal dust, even though wet, had aided in extending the explosion. The mine generated gas and the explosion apparently was preceded by a sudden outburst of methane. The face of the working place contained a big pool of water, and the management asserted that the mine was “naturally wet throughout,” yet coked dust was found on some of the ribs and props.

that of a 14-per cent mixture is only 30 cm. (11.8 in.) per second. A mixture of air with $6\frac{1}{2}$ per cent of ethane will propagate flame with greater speed than any mixture of methane. Fortunately ethane does not occur in coal mines.

The data mentioned in the preceding paragraph of course refers to a mixture of methane with pure air, which contains 20.9 per cent of oxygen. In mines the air is not pure. This leads to the question: what are the limits of inflammability of firedamp with impure air? And naturally it can be answered only in a general way by saying that the limit of speed is considerably reduced in air that contains much less than 20.9 per cent oxygen.

When the ignition point of a firedamp flame is at the open end of a tube which is closed at the other end, the speed of flame propagation is 140 times greater than that of a flame ignited at the closed end. If a gallery is open at both ends the most dangerous condition obtains for that condition favors a prolongation of the period of an explosion. In a gallery with one end closed, a partial vacuum is set up which tends to break the flame and extinguish the explosion.

A moving current of methane and air increases the speed of propagation of an explosion and develops the maximum pressure more quickly. When the velocity of the current is 75 cm. (29.6 in.) per second, the speed of propagation of an explosion is more than five times as fast as it is when the mixture is at rest prior to the explosion.

MANY DUST-EXPLOSION PROBLEMS UNEXPLORED

Many of the basic phenomena attending coal-mine explosions are yet in doubt, despite the years of study devoted to the subject. It is assumed that the laws which govern the propagation of flame in explosive-gas mixtures are applicable to explosive mixtures of coal dust and air. Nevertheless, we do not know such important details, as the exact effect of various conditions in the working places and galleries, and many of the physical and chemical actions relating to the bringing together of coal dust, air and ignition agents.

The speed of a molecule of oxygen is 350 m. (1,150 ft.) per second, which is in striking contrast to that of the gently floating particles of coal dust suspended in air. An analogy between the ignition of a mixture of gases with that of a mixture of coal dust and air therefore is not accurate. Consequently, generalities only may be dealt with.

Many coal-dust explosion tests have been made at the Eskmeals station in England within steel-tube galleries. The maximum pressure produced by a coal-dust explosion in a gallery of uniform cross-section is 50 lb. per square inch at a distance of about 500 ft. from the point of ignition. Three restrictions in the airway formed by the introduction of angle irons, so arranged as to reduce the diameter of the testing gallery by 1 ft., increased the pressure of the explosion at a point 450 ft. from the source of ignition to 152 lb. per square inch. Without these restrictions, other conditions remaining the same, the pressure is 16 lb. per square inch at a point 450 ft. from the point of ignition. Restrictive barriers in the testing gallery serve the same purpose as timbers in a mine to create turbulence and intensify the pressure caused by a coal-dust explosion.

Captain Steidle, Carnegie Institute of Technology, opened the discussion following the first lecture by asking what effect the fineness of coal dust had on the

propagation of an explosion. Dr. Wheeler replied that the finer the coal dust, the greater the speed and the greater the violence of the blast. The English standard of fineness for the coal dust used in tests specifies that 85 per cent shall pass through a 200-mesh screen.

J. T. Ryan asked whether gas in a bituminous mine could explode in the presence of coal dust without the latter entering into the blast. He was told that a gas explosion in all probability would raise a cloud of coal-dust which would combine with the gas and air to increase the intensity of the explosion. Though no tests have been made in England to prove this point conclusively, Dr. Wheeler is of the opinion that coal dust figures in practically every explosion.

DOUBTED IF VACUUM WOULD STOP EXPLOSION

Dr. Holbrook inquired whether a vacuum created at the closed end of a gallery would stop the propagation of a coal-dust explosion as it does one involving gas alone. Professor Wheeler did not think so, though he had no results of tests to prove his belief. To a question by G. S. Baton as to the effect of the volatile content of coal dust on the ignition and propagation of a flame, Dr. Wheeler said that higher contents of volatile matter increased the ease of ignition and the speed of propagation.

In Dr. Wheeler's second lecture on the prevention of explosions, he said that to eliminate many of these catastrophes in coal mines the surest procedure is to exclude the use so far as practicable of all potential means of ignition, or so control their use as to render them harmless. Blownout shots are the chief cause of explosions in England. The explosives causing them, unfortunately, have been approved by the Department of Mines. Dr. Wheeler commended the record established in this country in that no explosive approved by the U. S. Bureau of Mines has ignited firedamp on blowing out from a shot hole.

"It is flying in the face of Providence," he said, "to use other than permitted explosives in mines in this country." He asked, "Why the devil do you use that term 'permissible explosive' when you mean 'permitted explosive.'""*

Correctly designed flame safety lamps are incapable of igniting any mixture of firedamp and air, even though the velocity of the current is very high. An exposed filament of an electric cap lamp can ignite any combustible mixture of firedamp and air. Electric cap lamps of modern construction make the possibility of ignition remote unless they are damaged. Trolley wires create a hazard that cannot be harnessed.

Electric motors and controls are a means of ignition. They can be made flameproof by enclosing them within a casing. The English point of view differs from that of the American. The British strive to make a casing pressure- as well as flame-proof. An explosion inside a casing will burst it if it is not made sufficiently strong. Flame- and pressure-proof motors make for clumsy machinery. A hermetically sealed casing is the best assurance of protection against flame and pressure. The English are working on a flanged joint. It has been proved that a $\frac{3}{4}$ -in. slot gives the maximum release of pressure without allowing flame to reach the atmosphere outside the casing. A slot no wider than

*The answer is simple. For the U. S. Bureau of Mines to use the expression would be assuming the power of permitting or prohibiting other explosives, which under constitutional provisions, it does not have except in certain specific mines and on the Indian lands.

Dr. Wheeler, Messrs. Walker and Chapman with American Friends at Bruceton Mine

Taken during an exhibition test at the experimental mine made Friday, March 7. From left to right, John T. Ryan; A. A. Munsch, U. S. Bureau of Mines; Robert M. Lamble, chief, West Virginia Department of Mines; M. Morris, chief of rescue crews,

of that department; J. J. Paul, U. S. Bureau of Mines; Henry Walker, Deputy Inspector of Mines, Great Britain; Dr. R. V. Wheeler, Director of Mines Department, Great Britain; F. E. Cash, U. S. Bureau of Mines; W. R. Chapman, secretary to

Dr. Wheeler; George S. Rice, C. M. Bouton, H. P. Greenwald, A. C. Fieldner, all of the U. S. Bureau of Mines; Edward Steidle, co-operative mining department, Carnegie Institute of Technology, and H. C. Howarth, U. S. Bureau of Mines.

0.01 in. permits of a fair release of pressure. The margin of safety between these two limits is wide. Dr. Wheeler doubts if true frictional sparks are capable of igniting firedamp under mining conditions.

Even after all preventive steps covering the possible means of ignition described in the preceding paragraphs are taken at least two other agents must be made harmless—they are firedamp and coal dust. The former can be rendered harmless by adequate ventilation, but this often increases the hazard of the latter by stirring up dust.

Methane must be in excess of $5\frac{1}{2}$ per cent to propagate flame. A proportion of methane of $2\frac{1}{2}$ per cent is well on the safe side. It is questionable whether it is necessary to dilute methane by ventilation to a limit of $2\frac{1}{2}$ per cent. Some people advocate a further reduction, arguing that a $2\frac{1}{2}$ per cent indication of methane in one place may mean a higher methane content in another. On the other hand, a $4\frac{1}{2}$ per cent limit would give the same warning of danger.

GREAT BRITAIN RELIED ON WATER TOO LONG

No feasible quantity of ventilation will increase the volume of air to such a degree as to reduce the coal-dust percentage below the limit of inflammability. No more than 0.1 oz. of 200-mesh coal dust per cubic foot of air is required to propagate a coal-dust explosion. Many times that quantity is present in bituminous mines. Ventilation consequently does not remove this hazard. Coal dust is not an explosive in the same sense as black powder. It is dangerous only when suspended in the air as a cloud, and may be made innocuous by preventing it from forming a cloud.

Prior to the adoption of stone dusting, the wetting of mines was extensively practiced in England. When applied to the roof and sides of entries, water caused the former to become insecure and greatly increased the hazard of falling rock. The chemical composition of coal dust renders it difficult to wet down with water.

Solutions of several salts will wet it, but the arrangement is not any more practicable than to use alcohol, which also will wet coal dust. The quantity of water required in coal dust to make it comparatively safe is 30 per cent, though some coals may not need so much.

A coal-dust explosion is known to have occurred in a very wet English mine. Two shots within a short period of time and in close proximity to each other were directly responsible. The first shot released a pocket of methane which latter was ignited by the second shot. The flame traveled a short distance as a minor gas explosion and then increased to great violence. An investigation of the explosion showed that a skim of coal dust floating on water caused the continuance of the explosion, yet the entries were "swimming" in water.

EVEN 10 PER CENT OF ROCK DUST MIGHT HELP

In 1886, Sir William Garford suggested the use of rock dust to correct the tendency of coal dust to ignite and propagate flame. He had observed that airways, where practically only rock dust was found, checked explosions which had penetrated wherever coal dust lay.

Whatever efforts are expended in the direction of rock-dusting will do good varying in degree with the quantity of rock dust distributed. The addition of a small quantity of incombustible material will aid in reducing the violence and spread of the explosion. A mixture of coal dust with 10 per cent of rock dust is sufficient to reduce that violence to one-tenth. Pure coal dust in an explosion moves at a speed of 1,070 ft. per minute, producing a maximum pressure of 50 lb. per square inch. Coal-dust with 10 per cent of incombustible matter propagates a flame at a speed of 425 ft. per second creating a pressure of 4.8 lb. per square inch.

The most important English act relative to rock-dusting is that which specifies that the incombustible material in the dust in mines be maintained at 50 per cent by the addition of rock dust as needed. In some

instances, as much rock dust as has been specified may be necessary, in others, more is required. In the United States the mines may not have to maintain so large a percentage of incombustible matter to obtain an equal immunity. An addition of 10 per cent of rock dust is well worth striving for.

Small particles of coal dust are the most dangerous. To be most effective, the rock dust must be at least as fine as the coal dust with which it is mixed. In England 70 per cent of the dust must pass through a 200-mesh screen when it is to be distributed through the mine automatically, whereas when the rock dust is distributed by hand, if only 50 per cent will pass such a screen the dust will comply with the terms of the law.

GRANULES OF COAL MAY REDUCE EXPLOSIVE VIOLENCE

It is conceivable that granular coal mixed with fine coal dust will lessen the violence of an explosion. This conclusion seemed indicated by an investigation into the circumstances surrounding a certain English mine explosion. On the entries of this mine was strewn dust containing 80 per cent of incombustible material. A firedamp explosion at a working place soon spent itself

Rotary Dumps at Stag Canyon Mine

Note the full car on the right. At some mines such a carload would cause the foreman to reprimand the miner who loaded it but at the Phelps Dodge operation the miners are not allowed to build up the coal on their cars. Consequently the spillage, which makes rock dusting largely ineffectual, is avoided. The Phelps Dodge Co. had no rock dusting when this photograph was taken but they sought to reduce the quantity of coal dust in their roadways by ordering that their cars be merely "rounded on top."

along the rock-dusted entries. An investigation revealed the location of the source of the explosion. In its path was a patch of coal dust which was not ignited because it was intermingled with a considerable quantity of coal of the coarser sizes, the largest of which particles were about 1 in. in diameter. The mines in the United States after all may not have to add as much incombustible material as at first is expected.

It is not a difficult matter to reach the necessary saturation of rock dust. At the end of the first year of rock-dusting in a Yorkshire mine, samples at various points were taken yielding the following average percentages of incombustible material: 79.9 per cent on endless-rope haulageways; 67.5 per cent on other haulageways; 80.2 per cent on traveling ways; 68.4 per cent on return airways and 69.4 per cent on cross gates. In Table I is given a self-explanatory quantity study of rock-dusting in a South Wales mine.

Stone dust must be applied wherever coal dust is found in order to narrow effectively the limits of a local coal-dust explosion. Rock barriers are only a second line of defense; dusting is the first. Never should the barriers be used alone.

The health of a miner is not impaired by the use of limestone or a shale free of siliceous granules. Dr. J. S.

Table I—Effectiveness of Applications of Rock Dust in Maintaining Ash Percentage Required

Quantity Lb. Per Lin. Yd.		Number of Applications Per Annum	Quantity of Stone Dust in Lb. Per Lin. Yd. at Each Application	Percentage Ash Maintained
180	Roof, sides and floor	12	7	55 to 65
		36	2½	50
90	Roof and sides	4	22½	70
120	Roof, sides and floor	8	15	50
70	Roof, sides and floor	2	35	70

Haldane made what Dr. Wheeler termed a very favorable approval of the practice so far as health is concerned. The former reported that inhalation of the dust of soft stone is no more injurious than that of coal dust. Limestone is absolutely harmless, and by reason of its white color, it aids greatly in screening the light in the mine from the absorption effects of the coal, 98 per cent of the light that strikes the face being taken up by the coal. Thus limestone improves the illumination. Incidentally, the latter benefit decreases nystagmus, a common ailment of English miners. Gray shales are not so satisfactory.

That is how matters stand in England. They are satisfied for the time being and "are content to leave the security of their mines in the hands of stonedust," while scientists search for a better means of safeguarding mines than this "empirical remedy" affords. Stone dusting has been described by the latter phrase because nobody knows much as to the manner in which it acts.

DOES ROCK DUST MERELY COOL THE FLAME?

A discussion followed this second night's lecture. Dr. Wheeler is not satisfied that he knows just how rock dust prevents the ignition or propagation of coal dust. In answer to Edward Steidle's question on this point, he said, "One theory is that the particles of rock absorb heat and check the spread of flame."

Richard Maize wondered if a combination of suspended coal dust and firedamp below the lower limits of 0.1 oz. per cubic foot and 2½ per cent respectively, would cause an explosion if they could be ignited. Dr. Wheeler didn't know how such a combination might act together. Each of these lower limits is fixed without reference to the other.

A. C. Fieldner thought the audience would be interested in hearing how stone dust is applied. In response, Dr. Wheeler described briefly three common methods: (1) Shoveling by hand from tubs (mine cars) to roof and sides allowing the material to settle on the floor; (2) automatic distribution by dust car attached to the end of a train of tubs, power for blowing being derived from the moving axles of the tubs; (3) compressed air. This is used mostly in South Wales.

In addition to these methods, an unsuccessful attempt was made to apply the dust to the intake air, depending upon it to carry the dust. In one mine an interesting arrangement was devised in which a cloud of rock dust was directed toward a face while the latter was being shot down. This method is effective but hardly practicable.

J. W. Paul inquired as to the maximum quantity of explosive permitted in a single shot. He was told that only explosives on the British "permitted" list may be used and that the largest charge allowed is 18 oz. For coal, it is usually 4 oz.

C. L. Colburn recalled Dr. Wheeler's account of an explosion of a skim of coal dust on the water standing

in the entries of a very wet mine, and then asked what effect rock dust would have in a similar case. Dr. Wheeler said stone dust would absorb moisture and tend to drag down the skin of coal dust which otherwise would float on the water. He also let it be known that he has an aversion to adding more dust to an already dusty mine and would like to see a limited quantity of water added with the rock dust. He frankly admitted that many of his countrymen did not agree with him.

M. D. Cooper asked: "What arrangements are made by British mine owners for preparing or obtaining a supply of rock dust?" The lecturer described briefly the following schemes: (1) Dust ground in individual plants at the mine, using the "mortar-and-pestle" type of mill; (2) dust purchased from a commercial milling plant; (3) a partnership of several mine owners in a group milling plant. A recent development has been the use of a byproduct obtained in the manufacture of alkalines.

In answer to Alphonse F. Brosky's question as to why the fineness of rock dust is so specified that 70 per cent must pass through a 200-mesh when it is applied by machine, whereas only 50 per cent must pass this test when shoveled by hand, Dr. Wheeler said that the finer sizes are less injurious to health and more easily

Edward Steidle
Professor of mining engineering, Carnegie Institute of Technology, Pittsburgh, Pa. Captain Steidle has charge of the co-operative mining department maintained by his institution and fostered by the U. S. Bureau of Mines.

distributed by machines. In hand shoveling, larger sizes tend to clean off coal dust from ledges on the roof and ribs, allowing the smaller sizes of rock dust to settle there free of coal dust. Coarseness in size is more important in hand shoveling than is fineness in machine distribution.

J. T. Ryan asked if it would not be safer to leave coal dust on the floor of an entry than to shovel it up, when unmixed with rock dust, as the operation would raise a cloud of dust, much of which would settle on ribs and roof. Dr. Wheeler agrees that the loading out of coal dust with shovels makes a dangerous condition more dangerous. When rock-dusting is used, the continual addition of both coal dust and rock dust to that already on the floor must ultimately necessitate the shoveling out of the accumulated mass at more or less wide intervals of time. Flotation methods of separation are working

quite successfully to produce a merchantable coal dust and a byproduct that might be used again in the mines. He believes the Trent process well adapted to this separation.

Somebody inquired, "What percentage of the mines in England are using rock dust?" Dr. Wheeler's reply was, "Practically 100 per cent. There are, however, a few mines where this practice is not necessary."

Coal-Mine Accidents in Great Britain Take 1,289 Lives in 1923

In the coal mines of Great Britain there were 1,143 accidents, which caused the death of 1,289 men, in 1923, as compared with 1,026 accidents and 1,105 deaths in 1922, according to a preliminary report issued by the Mines Department. Major accidents of 1923 are shown in Table I.

Table I—Major Accidents at British Coal Mines in 1923

Date	Name of Mine	Nature of Accident	No. Killed
Feb. 22	Wheldale (Yorkshire)	Explosion of firedamp	8
Feb. 24	Medomsley (Durham)	Shaft accident (cage came out of guide due to worn shoes)	8
Apr. 24	Apedale (Staffordshire)	Irruption of water	8
Apr. 26	Trimsaran (Carmarthen)	Haulage accident (breakage of chain)	10
July 28	Maltby Main (Yorkshire)	Explosion of firedamp	27
July 28	Gartshore (Dumbarton)	Explosion of firedamp	8
Sept. 25	Redding (No. 23 pit) Stirlingshire	Irruption of water	40
Dec. 3	Nunnery (Yorkshire)	Haulage accident (breakage of rope)	2

The death rate at coal mines was somewhat higher than in 1922, particularly in the case of haulage accidents. Outside the Scottish Division, the deaths from this cause were about 50 per cent higher in 1923 than in 1922. The death rate at quarries in the Scottish and the Lancashire and North Wales Division was considerably higher than in 1922.

Table II shows the number of deaths caused by accidents in and about the mines of Great Britain (including those on private branch railways and tramways, and in washing coal) during 1923.

Last year, of the deaths from falls of ground, 392 occurred at the working face, 114 on roads while repairing or enlarging, 75 on roads while otherwise working or passing, and 4 in shafts.

Of the deaths from shaft accidents, 14 occurred while descending or ascending by machinery, 3 by falling into shafts from surface, 24 by falling from part way down, 2 by objects falling into shaft from surface, 3 by objects falling into shaft from part way down, and 12 by other shaft accidents, but no fatalities were caused by overwinding or by ropes or chains breaking.

The deaths due to accidents in haulage operations may be classified as under: Ropes or chains breaking, 11; run over or crushed by trams or tubs—mechanical haulage 105, horse haulage 75, hand haulage 23, run-away trams or tubs 73—total 276; other haulage accidents 25.

The deaths from miscellaneous causes below ground may be subdivided as follows: By explosives, 14; suffocation by natural gases, 7; irruptions of water, 52; electricity, 10; by machinery, 15; other accidents, 62.

Of the deaths on the surface, 21 were due to the use of machinery, 50 to accidents on railways, sidings and tramways, 2 to electricity and 41 to other causes. There were no deaths from boiler explosions.

Table II—British Coal-Mine Accidents in 1923 by Districts

	Explosions	Falls of Ground	Shaft Accidents	Haulage Accidents	Miscellaneous Underground	On surface	Total in 1923.	Total in 1922
Scotland	16	62	11	28	65	16	198	180
Northern	2	93	15	52	16	26	204	226
York & N. Midland	37	137	11	63	23	28	299	222
Lancashire & N. Wales	—	64	8	26	18	14	130	110

What Is the Relation of Cost of Production To the Price of Coal?

Efficiency of Management, Physical Conditions, Lost Time, Variation in Payments for Royalties and in Amounts for Depletion, Depreciation and Officers' Salaries Among Factors That Cause Wide Range in Output Costs

BY DAVID L. WING
Washington, D. C.

IN DISCUSSING underlying principles there are many things to be said that relate both to anthracite and to bituminous coal, but when the application of these principles is considered it is necessary often to make it clear just which industry and, in the case of bituminous, just which fields are under discussion. Such a variety of conditions exists that it will be found that what appears to be a similar result in two fields may have been produced by widely different causes.

First, let us consider the chief uses for cost-of-production information. These are two: its use to the operator and its use to the general public in its rôle of coal consumer. The practical use of a good accounting system to the operator in the conduct of his business is obvious and need not be stressed here. Events since 1916 have emphasized to the coal operator especially the importance of having adequate cost accounting to meet the requirements of the government.

In addition to the need for such information imposed on all industries to furnish information required for the federal income and excess profits tax, there also has been the special demand for it resulting from the price-fixing policy followed by the Fuel Administration during the war. The need of fixing prices that would sufficiently stimulate the production of coal, without imposing an undue burden on the consumer, made it essential to obtain adequate information on the cost of producing coal in the various mines in the different fields. It is from the standpoint of the public or consumer's interest in cost of production statistics that I wish to call attention to certain conditions of the problem involved. And I wish to emphasize the fact that in describing these conditions I am not advocating any particular method of solution.

WIDE RANGE IN PRODUCTION COSTS OF MINES

Since 1916, as a result of the strenuous career of the coal industry, a large mass of information on the cost of producing coal has been accumulated. For the years prior to 1916, however, little exists. In a paper that I read last November before the American Academy of Political and Social Science, I listed in some detail the various sources where this cost information can be found. One of the most striking facts shown in these statistics is the wide range in production costs found between mines in the same field and between different fields. The "Great American Average," if used with restraint, is helpful for certain purposes, but it certainly is a deadly expedient as often used in the discussions of the relation of costs of production to coal prices. This is because of the extreme range of those costs in a given field.

Paper read before the Washington Academy of Sciences, January, 1924.

Relatively few people, outside of those directly engaged in the mining of the industry, realize how great this range is. Some years ago, at my first appearance before one of the several Senate committees that investigated the coal industry almost continuously from 1917 to 1922, Senator Reed, of Missouri, sharply challenged my statement that the costs of production in the Pittsburgh field as shown by reports made by operators to the Federal Trade Commission, ranged, during September and October of 1917, from about one dollar to three dollars per ton. He then instructed me, on my return to the witness stand, to explain "how two coal companies, operating side by side, and selling in the same market, come to have such varying costs, one of one dollar a ton and the other of three dollars a ton." As there may be others who might wish to raise a similar question—one that goes to the root of the subject of price regulation, as well as that of reasonableness of prices, unregulated—I will give you my answer.

PHYSICAL CONDITIONS AN IMPORTANT FACTOR

(1) If mines are not under the same management part of the difference may be due to the relative efficiency of the respective managements.

(2) Physical conditions may be widely different in respect to:

Thickness of seam.

Pitch of seam—whether lying horizontally or at a difficult angle.

Purity of coal in seam—no sulphur balls, etc.

Faults and irregularities of seam.

Character of top and bottom of seam (determining the amount of timbering).

Type of operation, whether shaft or drift, and distance of productive seams from surface.

Drainage necessary.

Ventilation necessary.

Age of mine and character of mining—whether advancing rooms or robbing pillars.

(3) Time lost during month due to:

Car shortage.

Accidents to mine.

Labor troubles or labor shortage.

(4) Variations in payments for royalties and in the amounts of depletion, depreciation charges, and officers' salaries.

My experience, since then, in dealing with cost of production figures leads me to add two other important causes of differences. One is the relative use made in different mines of labor-saving machinery, which is expensive to install but which cuts down the labor cost per ton. Another is the relative amount of preparation that must be given to the coal after it comes from the mine before it can be marketed.

Now I must present a few figures, but I will be as brief as possible. First, however, a word as to the character of these cost statistics. The figures are the f.o.b. mine costs, compiled from sworn reports submitted by the operators to the U. S. Coal Commission, on monthly report forms prescribed by it. Many of the operators follow different accounting practices, which makes exact comparison of their figures impossible. The Coal Commission did not attempt to revise the cost figures to obtain greater comparability by reconciling different accounting practices. It preferred to use the figures sworn to by the operators rather than make changes for which adequate information on which to base them was lacking. While not 100 per cent comparable, the figures are undoubtedly sufficiently comparable for most practical purposes.

Since I have already mentioned the Pittsburgh field, I will give the range of costs there in 1921. Six per cent of the tonnage was produced at costs ranging from \$1.50 to \$2.20 per ton, and 9 per cent at costs ranging from \$3 to \$4.50, the costs of the remaining tonnage being spread out between those figures. The average cost was \$2.63 per ton.

Turning to anthracite costs, in 1921 it was found that the cost of fresh-mined coal (not including the product washed from the culm banks) ranged from \$3.75 to over \$12 per ton. That was the extreme range.

About one-quarter of the entire tonnage cost between \$5 and \$5.50, and of the 12 per cent of the entire tonnage which cost from \$6.25 upward, three-quarters was between \$6.50 and \$7.

These are the facts in regard to the range of costs of production. What relation have these facts to the prices charged by the operators? First, let us consider the uses to which the coal is put. As you know, the matter of market prices of coal is not wholly one of the cost of production—it is the resultant of two forces, the supply available at a given price and the demand for it at that price. It is necessary in measuring different factors often to make assumptions which simplify the complexity of the problem. But in any practical application this complexity must be recognized.

The price that the operator can obtain for his coal depends in part on the uses to which it can be put—for example, in metallurgy, for making gas, for blacksmithing, for fuel in households, apartments and office buildings in cities, for making steam for manufacturing or transportation. Also, do not forget that the operator's price is influenced by the availability to consumers of suitable coal from other fields or of other forms of fuel.

Now, what is the bearing of the wide range of costs in the matter of price fixing? Given an emergency such as rose in the summer of 1917, which caused the passage of the Lever Act and the establishment of the Fuel Administration, it becomes necessary to establish an artificial relationship between the cost of production and the operator's price. At such a time the demand for all fuel is so insistent that much of the effect of particular uses on price just described can be disregarded, because all the coal that can reach the

consumer is not sufficient to meet the demand for the use in which it meets most competition—that of making steam.

By governmental authority there is fixed an artificial limit of the maximum price which the operator in a field is permitted to charge. These field prices have to be fixed with relation to the costs of production in that field. The course the price fixer must steer lies between the Scylla of discouraging necessary production and the Charybdis of placing undue burdens on the consumer.

At such a time, in the attempt to fix a reasonable limit for maximum prices, the wide range of costs of production in a given field assumes great significance. The very conditions that have brought about the emergency requiring such action have already submerged, for the time being, the natural regulation on prices

caused by the free play of competitive forces. These, under normal conditions, regulate through the changes of supply to demand.

The wide range of costs enters the problem through the need of using as a price-fixing base not the average cost in a field but a cost above the average. Otherwise the production of too large a proportion of that half of the coal tonnage produced at a cost above the average will be checked. During the war the following plan was adopted in fixing maximum

coal prices: The first bituminous coal government prices were fixed by President Wilson's proclamation of Aug. 21, 1917, before the establishment of the Fuel Administration.

There was then in the possession of the Federal Trade Commission fairly reliable typical costs of production for nearly every important bituminous field east of the Mississippi. These costs were almost all in the form of what I may call average high and average low for the fields—what really amounted to ranges of the costs grouped around the 25 per cent and 75 per cent points of a percentage scale of costs ranging from low to high. They did not indicate the extreme ranges of costs. By President Wilson's direction, I applied the margin of 25c. per ton, which he decided was a fair margin, taking into consideration the conditions at that time, not to the *average field cost* but to the *higher cost*, which in most cases worked out at about the 75 per cent mark.

Later, under the Fuel Administration, the Engineers' Committee, using the thousands of detailed monthly cost reports made by the operators to the Federal Trade Commission as a basis, after a careful study divided up the original price-fixing districts, and established for each price-fixing district their so-called "bulk line cost," which was a price basis established at the 80 per cent mark. To this base line the margin which Dr. Garfield approved for that field was added, to obtain the field price.

In both cases it was necessary to take into account the wide range of costs and to establish field maximum prices which returned to some of the lowest-cost mines enormous profits (subject, of course, to the income and excess profits tax), while some of the high-cost produc-

THE matter of the market price of coal is not wholly one of the cost of production—it is the resultant of two forces, the supply available at a given price and the demand for it at that price. It is often necessary in measuring different factors to make assumptions which will simplify the problem. But in any practical application, the complexity of this question must be recognized.

tion, which had been stimulated by the runaway market prior to price fixing, was eliminated. The loss of this high-priced tonnage, however, was more than made up by the increased production of the lower-cost mines, stimulated by their large profits and helped by more adequate transportation facilities.

It must be borne in mind that the crisis which brought about the price regulation in 1917 was primarily caused by the inability of the coal to reach market, not by the lack of mining capacity or mining labor to produce coal enough to satisfy the abnormal demand.

A word about margins is necessary. The margin to which I have referred in connection with price fixing is not strictly a margin of *profit*. It is the figure which is obtained by subtracting the average per ton cost f.o.b. mine from the average sales realization received by the operator for all his tonnage sold during the period under consideration—month, quarter or year. From this margin must come federal taxes and interest on borrowed money, before the amount available for the owners of the business—profit in the sense commonly used—is known. Even then it cannot be translated into terms of per cent return on the investment until the investment per ton is known. And obviously this investment varies widely from operator to operator.

LABOR-SAVING MACHINERY LOWERS COST PER TON

Take, for example, two operators operating side by side under similar mining conditions. One operator uses pick mining and mule haulage; the other has a mine well equipped with mining machine, loading machines and electric haulage, all devices which cut down the amount of human labor involved in mining a ton of coal. The first operator will show a high labor cost per ton—because he uses human labor to hew down the coal, to load the mine cars, and to haul these cars with mules which require the guidance of many mule drivers. This means, of course, a much larger sum paid in wages for an equal output of coal than is paid by the operator who has the heavy investment in labor-saving machinery.

Under the accounting rules, the expense of the labor goes into the cost of operation. The cost of investment in labor-saving machinery, however, does not show in the cost of operations to any such extent. It is reflected in a relatively slight degree in the depreciation charge, that is, the allowance for the wearing out of all equipment in order that a fund can be accumulated for its replacement. But no allowance enters into the operating cost for the use of the heavy capital investment; no return on the money tied up all this time in this expensive labor-saving equipment. Thus the first operator might show a small margin because of his high cost brought about by his lavish use of human labor, while the second operator might show a large margin, due to his use of labor-saving equipment. And yet their ultimate return on the money invested might be the same. In any comparison of costs and margins these factors must be taken into account.

A word about the relation of large margins to high prices. It is true that in many cases individual operators have obtained large margins by obtaining prices far in excess of the average market prices. But it is equally important to remember that both in the anthracite and in the bituminous industry, operators also are to be found who have sold their output at prices below the average for the field and yet have obtained mar-

gins much in excess of the average margins for the field, whether considered in cents per ton, per cent of sales realization, or f.o.b. mine cost. The explanation lies in the low costs of such operations, due either to the natural conditions of their mines or to their heavy investment in labor-saving equipment. As concrete illustrations often are of more value than much generalization, the following may be of interest:

In a certain tabulation made for the Calder committee, and presented at the hearings before the La Follette committee—both Senate bodies investigating the coal situation—there appear for certain operators figures showing their investments, costs, sales realizations and margins during 1920. I wish to call attention to the figures of two of these operators, both in the Smokeless field in West Virginia. For the 21 operators shown, the average investment per ton was \$3.83, the average cost for the first 9 months of 1920 was \$2.87, sales realization \$4.64, and margin \$1.77 (which was equal to 62 per cent of the cost). The extreme range of margins shown for these 21 operators, all of whom had an annual production exceeding 100,000 tons, was from 56c. to \$3.90. They had been selected for the tabulation because of their relatively large margins between June and September, 1920.

Operator No. 1 had a production of about 370,000 tons per year (a cost of \$2.03, a sales realization of \$3.44, and a margin of \$1.41). His sales realization was 26 per cent below the average of the 21 operators, yet his margin was 69 per cent as large as his cost, as compared with 62 per cent, the average for the 21 operators. His investment per ton was \$6.07, as compared with the average of \$3.83, and his rate of margin received to investment was 21 per cent, as compared with the average of 47 per cent.

HIGH MARGIN NOT ALWAYS FROM HIGH PRICES

Operator No. 14 was a producer of about 250,000 tons per year. He showed a cost of \$2.01, a sales realization of \$4.22, and a margin of \$2.21. His sales realization was 9 per cent below the average of the 21 operators, yet his margin was 110 per cent as large as his cost, as compared with the average of 62 per cent. His investment was \$3.57 per ton, as compared with the average of \$3.83, and his rate of margin received, to investment, was 92 per cent, as compared with the average of 47 per cent.

It should be remembered that these 21 operators were picked on the basis of large margins shown for the four months of 1920 when a runaway market was at its height. Their figures are not necessarily typical of the whole field. For this Smokeless coal region, the Federal Trade Commission published 1918 costs for 176 operators, and the Coal Commission, for 1921-22, costs for 144 operators. But the example I have given illustrates the fact that high margin does not necessarily imply that it is derived from charging prices above the average level. And there are cases in anthracite as well as in bituminous coal where a sales realization that produces a relatively high margin actually is *below* the mine cost of a substantial part of the production of the field.

In closing I wish to emphasize the fact that in proportion as accurate and comparable information on costs and investments becomes available, it will be possible to ascertain more surely the relationships that should exist, for the welfare of the industry and the consuming public, between costs, profits and prices.

News Of the Industry

Castlegate Blast Due to Contact of Gas With Open Light, Says Preliminary Report

**Fireboss Believed to Have Attempted to Remove Firedamp from Room—
Not a Man Survives—All but One Body Recovered—
Compensation May Cost \$700,000**

Special Dispatch to Coal Age

Salt Lake City, Utah, March 17.—It is estimated that the Utah Fuel Co.'s Castlegate disaster will cost \$1,500,000 in compensation, repairs to mine, labor in recovery of bodies of victims and loss in operation during the next month. The compensation is now placed at \$700,000 instead of at \$1,000,000. The figures given are a rough estimate.

According to a statement issued by a joint committee of federal, state and company mine officials, following a preliminary and far from complete examination of the mine, the explosion appears to have been caused by the attempt of a fireboss to remove a small amount of gas from No. 2 room of the sixth left dip entry on the morning of the explosion. It was stated that indications found in No. 2 room of this entry pointed to the fact that gas had come in contact with an open light, immediately exploding, sending a wave of intense heat throughout the underground workings, which ignited other smaller bodies of gas, killed the miners and sent air rushing toward the main portal with such velocity that it was completely wrecked and pipes and timbers blown clear across the canyon.

To Seek Cause Definitely

Efforts will be made to trace the cause of the disaster more definitely, but following a day spent in the workings, Daniel Harrington, U. S. Bureau of Mines; B. W. Dyer, chief mine inspector; John Crawford, coal mine inspector, F. N. Cameron, vice-president and general manager of the Utah Fuel Co., and R. M. McGraw, superintendent, the above statement was issued. The report adds that all precautions appear to have been taken, that the rooms were well sprinkled, and that it will be some time before a definite decision can be made.

But one body now remains in the mine, and efforts to recover it are being continued.

More than 200 men trained in rescue work were gathered from mining camps within 30 miles of Castlegate on the day of the explosion. All sorts of obstacles hindered them. The mouth of the slope was choked with debris, there were many roof falls, and such volumes

of gas, soot and water were encountered that the first three days' heart-breaking labor, during which George Wilson a member of the Standard Coal Co.'s rescue team of Standardville, Utah, was asphyxiated, produced only 57 bodies. Day by day other bodies were brought out by the score until last Saturday when the total had reached 168. It was concluded by that time that the total number in the mine was 171 instead of the earlier estimate of 173, and that, therefore, only three more were to be found.

Although many of the bodies were mutilated beyond identification, some were found with watches ticking in their pockets. This apparent miracle is explained by a company official who thinks the jar of picking up the bodies would be enough to start a watch that had been stopped by shock. In many

cases, watches stopped at the exact moment of the explosion. By the end of last week, of course, the earlier hysteria in Castlegate had been succeeded by that funeral silence which always settles down over mining camps after such appalling shocks. Interment of dozens of men daily became a simple ceremony. A great ceremonial of sorrow, however, is planned for a day two weeks hence.

The first movement to raise a relief fund throughout Utah has been stopped. There appears no need for it. The company, which is a self-insurer under the law, expects to pay out about \$1,000,000 in workmen's compensation to the survivors.

Moderate Property Loss

The property loss to the company is said to be moderate, considering the fearful force of the blast. Many entries must be cleared, water lines and tracks relaid, some debris removed, and the mouth of the slope rebuilt, but outside of that the rehabilitation of the mine may not be extensive. While part of the fan house was blown out, the fan itself is said to be in easily repairable condition.

The main hoist also was damaged. A quantity of coal at the entrance of the mine was partly coked by the fierce

Hole Torn in Mountainside by Force of Explosion

Where one of the workings came near the surface the blast blew aside the light cover making an opening to the mine. The force was so terrific that not a single man in the mine lived to tell the tale. Fortunately the mine is so located with regard to the tippie that the men at work on the outside were not injured.

Rescue Squad Entering Castlegate Mine

Plenty of evidence of violence can be noted. Telephone and electric light poles, timber and pipes were blown across the valley, which is almost a mile in width. The second explosion blew a wall out of the fanhouse and the third partly wrecked the office building of the company.

blast which swept through the workings. Small fires were started in gob piles at various points underground but these have all been extinguished.

The dust in No. 2 mine of the Utah Fuel Co., at Castlegate, has been recognized as "the most abominable to contend with that has yet been tested by the Bureau of Mines." William Littlejohn, general superintendent of the company's operations, told the Rocky Mountain Coal Mining Institute about it at the February meeting of the Institute, in Denver. The danger of it, he said, was so grave that ironclad rules of protection against it were rigidly enforced in the mine. As this was written, nothing definite was known as to the part that dust played in the fearful tragedy of March 8, but Mr. Littlejohn's discussion of it, voiced three weeks before the explosion, is interesting.

Drench Places Before Shooting

Mr. Littlejohn said rules required that every working place be drenched before shooting. If a miner failed to do this, the shotfirer would refuse to shoot the place, he said. The use of permissible powders in the mine has caused enough flame to fire both the dust and gas feeders, he said. So precautions are taken against both. Here is a transcript of part of Mr. Littlejohn's discussion of a safety paper at the Institute meeting:

"It is my opinion there is no such thing as 'flameless powder.' We are using what is termed 'permissible powder' exclusively, and I know personally, having visited some of our working places and seen some very marked indications of the igniting of feeders by flame after shooting that permissible explosives do flame. We have two mines in our operations where we have to get the inspectors to go back and examine the working places for feeders.

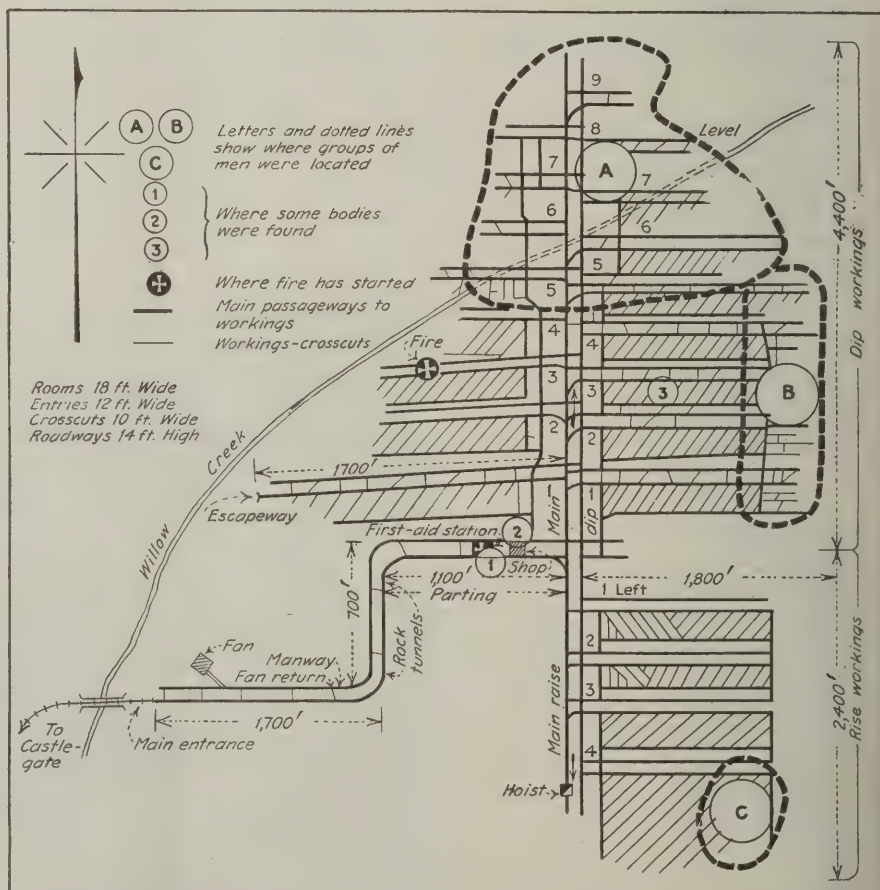

"It was an examination of No. 2 mine at Castlegate which caused us to change our methods. We found an entry which had been cut, drilled and sumped ready to shoot. When the shot inspectors returned after firing shots in this place they detected a strong

odor of burning. They sent for me and I went down there and made a personal examination. The whole situation was just as plain as daylight. We had eight shots, four in the entry and four in a crosscut. Unquestionably the four shots when they went off in the entry ignited dust. Unfortunately,

there was a shot right in the crosscut and evidently a tongue of flame projected and met the dust coming back from the face and ignited it. We got very distinct traces about 65 ft. back from the face. Fortunately, our mine was well sprinkled and it prevented a conflagration.

"We have a hard and fixed rule. Every miner must sprinkle his place. He is provided with a hose for this purpose. We have a strict rule and we live up to it. I want to say that we have—brother Harrington [Bureau of Mines' engineer] tells me—the most abominable dust to contend with that has yet been tested by the Bureau of Mines. If a miner goes home at night without sprinkling his place, the place is not shot. The shot inspector's instructions are to disconnect and don't shoot."

Mr. Littlejohn explained that he and several other mining men had devised sprinkler cars, two of which are regularly used in No. 2 mine. Each of these is a 1,200-gallon tank with a force pump and an arched pipe in front. The perforated pipe which throws the water is so arranged, he said, that roof and ribs are well washed down and even crossbars are soaked. "We sprinkle sides and roof regularly," he finished. "Mr. Harrington can tell you our sprinkling regulations are favorably known."

Skeleton Map Shows Where Men Were at Work When Explosions Occurred

The mine was developed according to the most up-to-date methods and every precaution except stone dusting was tried. The management at the mines initiated for America the practice of using non-combustible tamping and shooting coal electrically from a point outside the mine. It will be said that "another model mine has exploded"; but with this mine there is this difference: The management knew that it had a dangerous coal to deal with and that the air in the mine was so dry as to soak up water like a sponge, and consequently was never any too confident but was always looking around for additional means of protection.

District No. 2 Indorses Brophy Report In Stormy Convention at Altoona

About the only thing accomplished in the first five days of the convention of District No. 2, United Mine Workers which assembled in the Mishler Theater, Altoona, Pa., on Tuesday, March 11, and adjourned at noon on March 15 until Monday, March 17, was the indorsement of President John Brophy's policy relative to continuing the strike up to August, 1923, in the Somerset district, the threshing out of the controversy between President Brophy and T. D. Stiles, editor of the *Penn Central News*, and an address by Philip Murray, International vice president of the miners' union.

The controversy started over prolonging the strike in the Somerset region. Mr. Stiles took issue in his journal with the president on the policy he was pursuing, with the result that an injunction was obtained in the courts, tying up the labor paper and its business. When Mr. Brophy submitted his report, an open battle was waged, during which President Brophy, Vice President Marks and Mr. Stiles in turns engaged in a wordy battle which ended on Friday evening, when, by an almost unanimous vote of the delegates, Brophy was upheld in his stand.

Four hundred miners employed by the Vinton Colliery Co., at Vintondale, went on strike against a wage reduction and organized a local union on Monday. Brophy sent a telegram to Governor Pinchot requesting him to prevent eviction of miners from company houses. Educational and co-operative store movements occupied the attention of the convention Monday and Tuesday aside from a renewal of Stiles' defense of the *Penn Central News*.

Local Union No. 861, of Cresson, sent a resolution to the convention demanding impeachment of President Brophy, John Ghizzoni and John Kerr, who were responsible for the issuance of the injunction against the *Penn Central News*. This resolution went down when the convention accepted the Brophy report.

Miners at Marsteller sent a resolution which read: "Sign no scale agreement with the operators unless they agree to abolish the car push in District No. 2, said agreement to become effective not later than six months after said scale is signed." This will be considered at the conference with the operators on March 20.

It was decided to meet with the operators of the district in Philadelphia, instead of Altoona, on Thursday, March 20. Following are the men elected as members of the scale committee:

Territory 1, William Welch, Nant-y-Glo; Patrick McDermott, Hastings; territory 2, Harry Crago and H. E. Johnson, Philipsburg; territory 3, David Cowan, Portage; Faber McCloskey, Gallitzin; territory 4, Arthur Tayler, Robertsdale; Leonard Cleves, Defiance; territory 5, Herman Carletti, Punxsutawney; James Mottey, Elenora; territory 6, Peter Ferrara, Indiana; James McCarthy, Chambersville; territory 7, William Ackley and J. P. Nelson,

Madera; territory 8, Tony Badiala and D. P. Kirk, New Bethlehem; territory 9, S. J. Hudvinski, Morris Run, and J. G. Haskins, Blossburg.

In his address before the convention, Vice-President Philip Murray emphasized the importance of maintaining contractual obligations.

"We believe that a three-year contract will do much to stabilize the mining industry and that it is the best wage contract that has ever been adopted, both for the miners and for the industry," is the way Mr. Murray put it in speaking of the Jacksonville agreement. He declared that many new operators have come into the industry in late years, with the result that the industry is economically unsound and marked by cut-throat competition, with wage reductions in the non-union fields. He said: "Many of these operators are unable to pay their men and failures among them are frequent and they have thrown the whole industry out of gear."

The report of Secretary Richard Gilbert was a voluminous affair, every item being of interest to the miners of the district. The report shows a membership in the district of 42,799, a decrease of 6,974, due, he said, to conditions in the Somerset field. There are 235 local unions, a decrease of 25. The tax paid in 1923 amounted to \$1,108,892.98, while assessments totaled \$661,170.26. There was paid out in strike donations from April, 1922, to December, 1923, \$1,326,809.87.

The number of checkweighmen employed during the year was 412, and the amount of wages paid was \$498,711.63. Death claims were paid for 424 members and 232 widows or widowed mothers to the amount of \$108,000.

The receipts from all sources during the year, including the balance from 1922, were \$1,909,873.28, and the expenditures were \$1,542,348.63.

To Discuss Mine Problems at A. I. E. E. Convention

The spring convention of the American Institute of Electrical Engineers, to be held at Birmingham, Ala., April 7-11, will devote a session on April 10 to coal-mine problems. The papers to be read and discussed at this session are as follows: "Electrical Safety in Coal Mines," L. C. Illsley, U. S. Bureau of Mines; "Automatic Substations for Mines," C. E. Von Sothen, General Electric Co.; "Tests on Mine-Hoist Control," F. L. Stone and F. R. Grant, General Electric Co.

Sign 3-Year Agreement In Washington State

The union operators in the State of Washington and the United Mine Workers agreed Saturday, March 8, to a renewal of the existing wage contract for a period of three years from April 1, 1924.

British Miners Reject 10 per Cent Wage Rise; Ask 20 per Cent Advance

Delegates representing 750,000 British coal miners have unanimously rejected the mine owners' offer of an increase of 10 per cent in the minimum wage, which would be 30 per cent above the 1914 level, demanding an advance of 20 per cent in the present scale. Negotiations have been broken off and the Miners Federation will concentrate its efforts on the labor government and Parliament to obtain accession to their demands by means of the minimum wage bill which will come before Parliament March 21. If this move does not meet with success the miners' delegates will assemble on March 26 to decide on a ballot for a nationwide strike of coal miners.

Wage Troubles Vex Eastern Kentucky Fields

It is reported from Whitesburg, in Letcher County, eastern Kentucky, that there have been some sweeping reductions of 20 per cent posted in wage scales in the greater portion of the Elkhorn or northeastern Kentucky coal territory. Louisville coal men assert that there has been a lot of rate reducing in eastern Kentucky, until it is uncertain as to whether wages are now at the 1917 wage scale or below. Indications are that some of the non-union districts are below that figure.

Southeastern Kentucky, which is not fully unionized, has balked on signing a three-year contract, or operating on the present wage scale, feeling that it is suicide to do so in view of the competition from the eastern and north-eastern sections of the state, where the most powerful combinations are located. The non-union sections of eastern Kentucky also are largely responsible for the feeling of western Kentucky in opposition to a three-year scale or renewal at the 1919 basis.

Deadlock in Wage Parley Of Western Kentucky

Apparently there is a deadlock between committees representing District 23, United Mine Workers, in western Kentucky, and the Western Kentucky Coal Operators' Association, in the conference at Louisville to draw up an agreement to take the place of the one expiring on March 31. The miners, it is said, are holding out not only for a renewal of the expiring two-year scale agreement but for a three- or four-year agreement at the existing scale. The operators want a reduced scale and a contract of not more than one year, or two years at the outside, it is said.

Operators assert that with the non-union fields running coal freely, and adverse traffic or freight rate conditions, the western Kentucky field is at a disadvantage, and can't successfully pay the Central Competitive scale of 1919 and operate. The union leaders, it is said, are holding firmly.

The meeting began on March 11 and adjourned on March 14, to resume on Tuesday or Wednesday of this week.

Agreement Near at Baltimore

Agreement on a wage scale seems near between the Northern West Virginia Coal Operators' Association and the United Mine Workers as *Coal Age* goes to press. The conference, which began March 11 at the Southern Hotel, Baltimore, adjourned March 15, to meet again March 19.

George S. Brackett, vice-president of the operators' association, said the joint subcommittee had reached an agreement on many disputed points on working conditions on Saturday morning. At the conference on Wednesday it is expected that the subcommittee will be ready to submit its report, when it is hoped that an agreement will quickly be reached.

Judge Williams Advises Issue Of Trade Statistics

The essentiality of the trade association and of trade statistics was pointed out in an address by Nathan B. Williams, associate counsel of the National Association of Manufacturers, at the annual convention of the Refractories Manufacturers' Association at St. Louis, March 19. Among other things, Judge Williams said:

"Trade associations are tools of industry. There are those who would outlaw them. Being tools of industry, they must be kept in condition to perform their proper and useful functions.

"The trade association is the primary source for accurate information respecting a particular industry or trade. By means of the association not only is the industry and its constituent elements informed but the public as well is made aware of that essential information which must necessarily be known in order that both business and government may function successfully. The trade association is the legitimate, the obvious and the fundamental agency to gather, prepare and disseminate this information.

"The collection and publication of unidentified current trade statistics are not unlawful. Trade statistics and other trade information may be misused, and when so misused, subject those who perform such illegitimate use to the pains and penalties of the laws in such cases made and provided.

"In my judgment legitimate trade associations should continue their statistical and other activities without reference to the correspondence between the Attorney General and the Secretary of Commerce, and in conducting their activities be careful not to transgress the well-known inhibitions of existing law, in that they not misuse their statistical and other trade information in promotion and furtherance of any agreement or conspiracy to fix prices, limit production, restrict sales, divide territory, or otherwise restrain lawful competition in commerce.

"Accurate and complete cost accounting is vitally necessary to all business, not merely as a guide to business conduct but in complying with state and federal income tax laws.

"Government is but the organized expression of the intelligent judgment of the citizen. The trade association should be the means, the opportunity,

Alexander Howat

Indicted and imprisoned for calling a strike. U. S. Supreme Court refused to accept Mr. Howat's plea that Kansas had no right to pass the Industrial Relations Court Act making coal mining an essential industry.

and the vehicle for such expression. In just the degree that those who have most at stake in society, most to be preserved by orderly, reasonable and intelligent government, see to it that that government measures up to the requirements demanded in the successful conduct of business enterprise, will our institutions and security be protected and our institutions, social, political, and industrial, be promoted and preserved."

British Mine Safety Expert Studies Coal Industry Here

Dr. R. V. Wheeler, who is in charge of the British government's research dealing with safety in coal mines, is being given some impressions of the American coal industry on a trip arranged by the Bureau of Mines. He is accompanied by George S. Rice, chief mining engineer of the bureau. The limited time at Dr. Wheeler's disposal necessarily has made the trip a hurried one.

Dr. Wheeler, Mr. Rice and members of their party were entertained at a luncheon in Chicago March 11. The day following was spent at the bureau's station at Urbana, Ill. March 13 and 14 were spent in inspecting mines in the region near Benton, Ill. St. Louis was visited on March 15. The party reached Detroit March 17 and visited the lead bath process at the Ford plant and inspected some of the processes of the Combustion Engineering Co. The remainder of the party's itinerary is as follows: March 18, Niagara Falls; March 19, Schenectady; March 20, Scranton; March 21, Wilkes-Barre; March 22, conference in Washington at the U. S. Geological Survey on the constitution of coal and its microscopic examination; March 23, Washington; March 24, 25 and 26, southern West Virginia; March 28, conference in New York with Dr. R. B. Moore and at the Trent process plant. Dr. Wheeler will sail March 29 on his return to England.

Trade Commission Authority Limited, Says Supreme Court

The Federal Trade Commission has no authority to demand all documents and papers from a corporation in an effort to obtain evidence of unfair practices but must confine its demands to such documents as are evidence, the U. S. Supreme Court held March 17 in a decree which further restricts the commission from so-called "fishing expeditions" into business.

The decision, which was read by Justice Holmes, was in the appeals of the commission from decisions of the district courts in sustaining objections of the American Tobacco Co. and P. Lorillard Co., Inc., to obeying a general order of the commission to produce "all records, contracts, telegrams," etc., in connection with tobacco purchases and sales in 1921. The order was in response to complaints lodged with the commission and also in response to a Senate resolution directing an inquiry by the commission into tobacco sales and other affairs, with particular reference to prices paid producers.

In its decision, the Supreme Court, upholding the action of the lower courts, said:

"It is contrary to the first principles of justice to allow a search through all the respondents' records, relevant or irrelevant, in the hope that something will turn up. The right of access given by the statute is to documentary evidence—not to all documents but to such documents as are evidence. The analogies of the law do not allow the party wanting evidence to call for all documents in order to see if they do not contain it. Some grounds must be shown for supposing that the documents called for do contain it.

"The investigations and complaints seem to have been only on hearsay or suspicion—but even if they were induced by substantial evidence under oath the rudimentary principles of justice that we have laid down would apply. We cannot attribute to Congress an intent to defy the Fourth Amendment or even to come so near to doing it as to raise a serious question of constitutional law."

The opinion did not discuss whether Congress could go this far if it tried.

Johnson Immigration Bill Reintroduced in House

The Johnson Immigration bill was reintroduced in the House of Representatives at Washington March 17, retaining the 1890 census as a basis for a 2-per cent quota, but otherwise revised to meet the suggestions of Secretary Hughes relative to treaties and administrative features. By retaining the 1890 census the Japanese clauses remain unchanged.

As the 3-per cent quota law will expire June 30, enactment of permanent legislation is hoped for before adjournment, which is expected about June 1. Hearings before the committees of both houses of Congress have dragged for so long, however, that its enactment will seem seriously threatened.

Rapid Growth of Interconnection of Power Means Much to Coal Industry

Studies Prompted by Secretary Hoover Reveal Amazing Progress in Linking Up of Electric Lines—Ruling in Industrial Court Case May Have Far-Reaching Effect

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

Special studies being made of the superpower situation at the instance of Secretary Hoover reveal that the progress in interconnection of electric lines is proceeding at an amazing rate. The extent to which interconnection has been taking place has not been appreciated entirely because this is the first time that data covering this situation throughout a large area have been brought together at one place. The information submitted by the states has been combined with that of the federal government and mapped. These maps, which are being prepared by the Federal Power Commission, are destined, it is believed, to be the focusing point of a large amount of attention during the next few months.

The rapid trend toward interconnection has an important bearing on the coal industry. Its chief importance unquestionably is that it is making for consolidations and concentrations within the industry, which is moving more and more rapidly toward a vast public service. The ruling of the Supreme Court of the United States in the Kansas Industrial Court case has an important bearing in that connection. In that decision, the court implied that the only kinds of businesses in which the state may step in and compel arbitration, the acceptance of awards and other drastic forms of regulation are those universally regarded as public utilities. The next few years, in the opinion of high authority in Washington, is certain to show great integration of coal mining and power production. If this does not result in outright ownership, it will be effected by the strongest types of contracts.

The survey now in progress shows that the great electric utilities are pushing out their lines with great rapidity and are displacing large numbers of steam plants operated as a part of the individual establishment. It already is indicated, according to the engineers who are studying this problem, that some day in the future the great service of supplying power will be located largely in great plants as near the source of coal supply as a supply of condensing water will permit. The great agencies which will distribute this power are not going to invest millions of dollars in steam plants without insuring themselves absolutely as to coal supply. The steel companies have long followed the policy of purchasing reserves of coke and coal. It is certain that these great central stations are going to safeguard their supplies of steam coal in much the same fashion. In that connection it may be remarked that the study of interconnection has progressed far enough to indicate that chief reliance in the industrial area of the Atlantic

seaboard must be placed on electricity generated at steam plants.

With enormous pools of power in concentrated ownership and with the bituminous-coal deposits in the hands of relatively few interests, it is obvious that coal will be brought more and more into the class specified by the Supreme Court as being properly subject to regulation.

Dorchy Decision Significant

Since the Kansas Industrial Court case has such significance to the coal industry, it may be well to point out here that the court's decision on March 10 in the case of August Dorchy versus the State of Kansas is in no way a reversal of the position taken in the Kansas Industrial Court case. The industrial court case was decided last June. In that decision the Supreme Court held that the scheme of compulsory arbitration in essential industries is unconstitutional on the ground that to fix wages or prices of products is a deprivation of the right of contract guaranteed by the Constitution. In that decision, the court made the famous parenthetical statement that since the adoption of the Constitution "it never has been supposed that the business of the mine operator or the miner was clothed with such a public interest that the price of his product or his wages could be fixed by state regulation." It then went on to imply that an industry must be absolutely in the public-utility class before it could be subject to regulation and that when capital or labor enter such public-utility services they give an implied pledge for continuous service.

Before that decision was handed down, August Dorchy and Alexander Howat had been put in jail by the Kansas Industrial Court for having called a strike at a Kansas coal mine. The case was appealed by the union to the Supreme Court of Kansas. That tribunal upheld the state law. The union then appealed to the U. S. Supreme Court. All of this took place, however, before the Supreme Court's decision in the Kansas Industrial Court case. The Supreme Court of the United States realized that the decision of the Supreme Court of Kansas would have been affected had its opinion been available when the Dorchy case was before it. All that is done in the Dorchy case is to return it to the Supreme Court of Kansas so that that tribunal may have an opportunity to pass on it in the light of the Supreme Court's action in the preceding case.

The language of the decision can be construed to mean that the state court may still hold that the Kansas Industrial Court has the power to jail a man for inciting a strike even though it has not the power to compel arbitra-

Miner to Represent King At Holyrood Castle

The British Government has decided to appoint James Brown, Socialist member for South Ayrshire to the post of Lord High Commissioner to the General Assembly of the Church of Scotland. Brown, who is a coal miner, will leave his £10-a-year cottage to dwell for a few weeks each year in historic Holyrood Castle, home of the royal Stuarts. Royal salutes will be fired in his honor, and his wife, a former mill girl, will be addressed as Your Grace. And when it is all over they will go back to their cottage of two rooms and kitchen.

For two and a half centuries the post has been held by the Scottish nobility. It is the duty of the Lord High Commissioner to act as representative of the King during the General Assembly of the Church of Scotland and to occupy the state apartments of Holyrood Palace during that time.

tion. Whether the state court will insist on its former view, in spite of the Supreme Court's decision, remains to be seen. So far as the layman can penetrate the mysteries of the legal mind, it seems apparent that the Supreme Court still believes that the production of bituminous coal is not a public business and that the public cannot interfere to fix the price of the commodity or to compel men to cease striking. Whatever the court may have said about the relatively unimportant mines of Kansas probably would not be repeated were it dealing with a great service of coal and power such as those toward which we are headed in the North and East. The opinion is held in impressive quarters that regulation must be taken into account as we trend toward superpower.

Michael F. Burns Retires From Coal Company

Michael F. Burns, president of Burns Brothers Coal Co., of New York City, and head of the company since its organization, retired from the corporation March 12, when he presented his resignation to the board of directors, effective April 1. A special meeting of the board of directors of the company was called for 3 p.m. to consider Mr. Burns' action.

Differences of opinion regarding the management of Burns Brothers' affairs are understood to have existed since an attempt was made last year to nationalize the company by expanding its operations to other cities. This failed at the time, but it is believed that it may be taken up again should a new president be elected who is friendly to the interests not overfriendly to the present management.

Frank L. Burns, a son of M. F. Burns, is still with the organization.

Brydon Urges Legislation Against Labor Monopoly

Addressing the League for Industrial Rights, at the Waldorf-Astoria, New York City, March 7, on "The Trend of Labor in the Coal Industry," John C. Brydon, president of the National Coal Association, traced the growth of the United Mine Workers, paying particular attention to that organization's course toward militancy.

"The change from craft unionism to industrial unionism, the abandonment of the principle of arbitration of industrial disputes, and the increasing denial of the rights of capital, operating as they do, not in the coal industry alone but in the American Federation of Labor as well," said Mr. Brydon, "are dangerous.

"The institutions of this country have always been hostile to the existence of monopoly, whether of capital or of labor. Any system which has for its object the setting up of a monopoly of labor, subject to no control other than the whims of its politically chosen leaders, and which denies the right to work to any man who does not subscribe to the tenets and contribute to the funds of that organization, is an anomaly in the American scheme of things. It is toward this goal that unionism in the coal industry is tending, and I think you will agree with me that this is a most unfortunate circumstance.

"Abolition of the United Mine Workers would be a serious mistake. I believe in the right of man to organize and bargain collectively, provided they can find employers who will contract with them in that manner. I also believe that an individual has the right to stay out of an organization and has the right to work under such conditions if he chooses, and I believe further that the employer has the right to choose whether he will contract with the union or not.

"The best solution of the problem is by the effective force of public opinion, which will outspokenly condemn these undesirable developments.

"There are at least two lines along which the force of this aroused public opinion should make itself felt. In the first place, it should insist upon such legislation as will make the United Mine Workers legally responsible for living up to their contracts. At the present time the scale contracts in the coal industry really bind only one party, the operator; and there is an almost unbelievable record of strikes in violation of contract. If the United Mine Workers are to be allowed to continue to make wage contracts for 60 per cent of the bituminous coal industry, they must be made to live up to those contracts.

"In the second place, if the miners' organization is to continue to wield the vast power which results from nationwide combination, it must be made to recognize the principle of arbitration. The expiration of wage contracts must not be a signal for the employment of the tremendous economic power of that combination against the public. If such combination is to be permitted, it is essential from the standpoint of the

Label: Laugh Here

The pre-prohibition story about how he put whiskey in a fan water gage to keep it from freezing was not the only funny one E. H. Weitzel, general manager of the Colorado Fuel & Iron Co., told the Rocky Mountain Coal Mining Institute at its February meeting. There also was the one about the mine boss who was having trouble at home and who decided to "take her some flowers and call her 'dear' again." He did. She misunderstood. "Ain't it enough for Mabel to skin her leg and Mary to take the measles and the soup to burn today," she bleated, "without you comin' home drunk?"

public interest that it carry certain limitations. Chief of these limitations must be the recognition of the principle of arbitration as a means of settling industrial disputes. An aroused public opinion can bring this reform about; and it must be brought about, if the interest of the public is to be protected."

Strike Looms in Alberta

Negotiations on a new wage scale in District 18 (Alberta) between operators and district officials of the United Mine Workers were definitely broken off Saturday, March 15, the conferees being unable to come to an agreement. As the present agreement expires April 1, the possibility of a strike is uncomfortably close.

Consolidation in the Wind At St. Louis

A consolidation of the Southern Coal, Coke & Mining Co., with six Illinois mines, and the Donk Brothers Coal & Coke Co., with four, is the talk of the coal and financial circles of St. Louis, Mo., where both companies have headquarters. The deal has not been completed, however, and nobody knows yet whether it ever will be, logical though such a grouping would be in some particulars.

An important official of one of the companies said on March 14: "We cannot deny, of course, that a merger has been in contemplation. The details have not been finally concluded, however, and we must await such conclusion before we can give out anything concerning the subject."

It was reported that the Consolidated Coal Co. of St. Louis, headed by Kingdon Gould, of the Missouri Pacific Ry. interests, also was figuring in this consolidation, but W. J. Jenkins, vice-president and general manager, nailed this with a flat denial.

Most of the properties involved in the proposed consolidation are in the Standard district of Illinois immediately east of St. Louis, where few mines earned any money during the past year and where many companies are having hard sledding. Other consolidations and sales of mines are reported as taking form among such mining companies.

Pennsy to Take Over N. & W.; Three Want Virginian

A conference of committees representing the Norfolk & Western and the Pennsylvania railroads will be held soon to consider the leasing of the Norfolk & Western to the Pennsylvania, N. B. Maher, president of the Norfolk & Western, having announced that the first definite steps in the transaction had been taken by the Pennsylvania road.

"Following a special meeting of the directors of the Norfolk & Western," Mr. Maher said, "a communication was received from the president of the Pennsylvania R.R. suggesting the advisability of the lease of the Norfolk & Western by the Pennsylvania on terms which would preserve the operating identity of the Norfolk & Western.

"The Norfolk & Western was authorized to appoint a committee of the board to confer with a similar committee of the Pennsylvania R.R. board to see if such a lease could be negotiated and to report back to the board. If terms can then be agreed upon the matter would then be presented to the Interstate Commerce Commission."

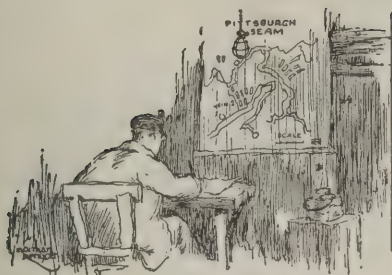

A report was circulated that the Pocahontas Coal & Coke Co. might be segregated from the Norfolk & Western R.R. before putting into effect the lease. It was stated also that a number of other operating changes would have to be made on the Norfolk & Western before leasing the property to the Pennsylvania.

The Baltimore & Ohio and the New York Central are bidding against each other for the lease of the Virginian Ry., each of the systems desiring to get control of the valuable coal fields on the line of the Virginian. The Chesapeake & Ohio R.R. also is anxious to obtain control of the Virginian, but it is said that the propositions from the New York Central and Baltimore & Ohio are more attractive to the heirs of the late H. H. Rogers, who founded the road.

As the leasing of the Norfolk & Western by the Pennsylvania is believed to be only a matter of days, the Baltimore & Ohio is eager to obtain the Virginian because it is feared that this road eventually may be taken over by the Pennsylvania. The Virginian is the Norfolk & Western's greatest competitor and has cut into the profits of that system by building great coaling piers on Hampton Roads. The Baltimore & Ohio almost closed a lease with the Virginian a year ago, but negotiations were broken off when a daughter of the late H. H. Rogers refused to relinquish her holdings.

Trade Commission Hampered By Lack of Funds

Lack of funds and personnel has hampered the work of the Federal Trade Commission according to report to the U. S. Senate March 11 in which the commission announced that it will not be able to carry on its work unless relief is extended. The work of the commission in conducting its numerous investigations into unfair trade practices is six months in arrears, the report stated.

Problems In Underground Management

Lining a Shaft With Precast Concrete

Shaft Relined from Bottom Up—However, Cross-Buntions or Side Slabs Embedded in Rock Will Support Weight When Lining Is Being Extended Downward

By A. B. DOWELL
St. Louis, Mo.

In the retimbering of a shaft for the Cameron Coal Co., near Pittsburg, Ill., precast reinforced concrete slabs were used in place of timbers to form the curbing or lining of the shaft.

The shaft thus retimbered was 258 ft. deep and measured 10 x 18 ft. in the clear. In Fig. 1 is shown a view of the headframe and engine house adjoining, taken during the progress of the work. For certain reasons the relining of the shaft was started from the bottom, and a few of the slabs are seen in the foreground ready to be lowered into the shaft.

When this plan is adopted, a good foundation is sought for the first slab placed in position. Only such of the old timbers were removed as was necessary to make room for the concrete slabs, which are built up one on top of another. As each set of slabs forming a course is placed in position, the space behind is well packed and rammed with sand or other loose material that will form a solid support for the strata.

CAN LINE UPWARD OR DOWNWARD

The relining of a shaft may be commenced at the top and proceed downward, although there is some advantage in starting the work at the bottom and building up. This order of

procedure affords a better opportunity for packing the loose material behind the slabs as they are placed in position. In the sinking of a new shaft, the work must naturally start at the top and be carried downward as the excavation proceeds. It is important then to furnish adequate support for the lining during the progress of the work. This is best accomplished by providing cross-buntions embedded at suitable intervals in the solid strata, or by extending the slabs so that they will rest in niches of similar character.

In Fig. 2 is shown a large number of concrete slabs that have been cast in the required shape ready to be taken to the shaft. In the left foreground can be seen a few courses of these slabs built up in the form in which they will stand when in position. It will be observed there are two hoisting compartments separated by an open partition that serves to strengthen the longer slabs in the face of the shaft and provides support for the cage guides. At the farther end is seen a smaller compartment, which forms the manway and in which the column pipes for the pumps and power cables can be installed.

These precast concrete slabs were manufactured under the Dowell patent. The concrete mixture was formed of

Fig. 2—Concrete Forms in Storage

From the structure in the foreground, laid up merely for exhibition purposes, an idea may be formed of the way in which the concrete units are arranged in the shaft.

the best quality of portland cement, one part; clean sharp sand, two parts; and selected gravel, three parts. Steel rods are used for reinforcing the slabs.

AS READILY HANDLED AS TIMBERS

After the concrete liners had been precast on the surface, they were handled much as timbers would be if used for the same purpose. The slabs form a tight skin-to-skin casing and when properly sealed, this lining affords an absolutely dry shaft, water being entirely excluded. In the instance mentioned, the shaft was very wet, but that did not materially interfere with the work of placing the slabs.

In order to obtain a watertight lining, proper care should be taken in sealing the joints. The construction or precasting of the concrete slabs is practically the same, in cost, as the framing of the necessary timbers; and the cost of handling and installing the slabs does not exceed that of handling the same quantity of timber curbing.

One of the chief advantages of the use of reinforced concrete slabs is the durability of the work when the installation has been properly performed. The natural hazards relating to shaft lining are reduced to a minimum and the construction provides a smooth surface that practically eliminates the danger of wrecks in the shaft caused by the catching of the cage in loose timbers.

By the use of the precast method the cost of building forms in the shaft is saved and the work of lining greatly simplified. The building trade after many attempts to cast concrete in place now uses it only where the work is heavy or the wall is readily braced exteriorly as for instance in lining a cellar or building a house foundation.

Fig. 1—Hauling Precast Units to Cameron Shaft Near Pittsburg, Ill.

The concrete units shown are buntions which stiffen shaft walls and sustain the cage guides. As the slabs and buntions are cast on the surface with all conditions favorable each unit is more nearly perfect as to reinforcement and freedom from voids than concrete not so constructed.

Practical Pointers For Electrical And Mechanical Men

Thaw Frozen Water Pipes By Electricity

Temperatures in the mines are generally considered to be nearly constant throughout the whole year. However, every one who has ever been in a mine knows that there are certain places where the mine temperature is the same as that outside. This is especially true where the coal bed is not very deep, or where the ventilating air enters the mine.

The foot of a hoisting shaft is another such place, and because it is often located in the basin of the coal bed it is not infrequent to find that water can be easily collected there. Consequently pumps used to pump this water operate under conditions which are very similar to those outside and may become frozen.

Coal companies which own many of the houses located around the mine frequently find themselves very busy during the winter months in thawing out frozen water lines.

For just such conditions as these, our company designed and built a transformer to be used for thawing out frozen pipe lines. Incidentally, this same transformer has been very serviceable whenever we desired to make high current tests on equipment. The transformer was built in our own

Connections Used When Thawing out Centrifugal Pump and Pipe Lines

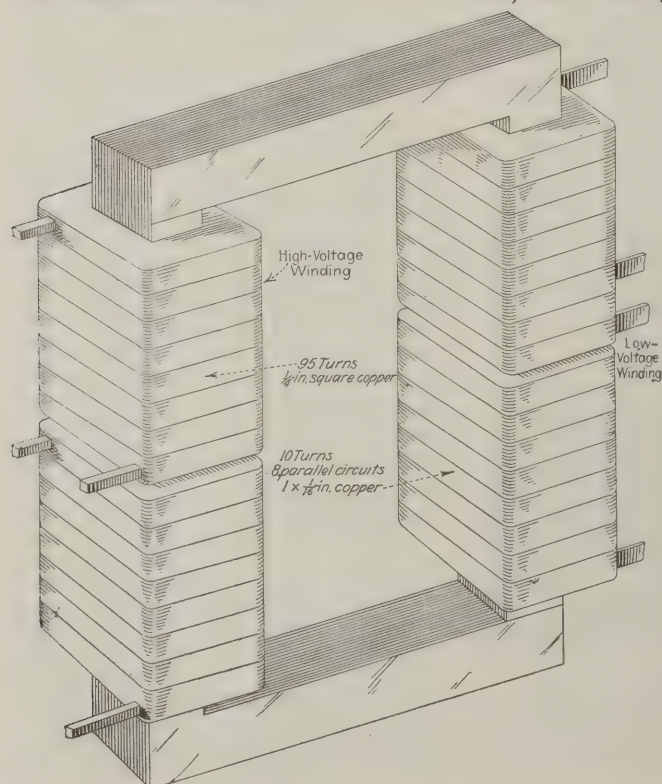

In less than three hours the pump and pipe lines which were frozen throughout the entire length of 120 ft. were thawed out and the pump again ready for service. This method of thawing out the pipe line was much more efficient than any other.

shops and is constructed with a core having a section 4 in. x 4 in. The long side of the core is 32 in. and the short side 12 in. The high-voltage winding is made up of two coils, each having 95 turns of $\frac{1}{8}$ in. square copper. The low-voltage winding is made up of two coils, each having eight parallel cir-

cuits of 10 turns of 1 in. x $\frac{1}{8}$ in. flat copper. The high-voltage winding was designed for either 110 or 220 volt, and the low-voltage winding designed to give about 1,000 amperes at 25 volts, or 2,000 amperes at 12.5 volts.

A few days ago, a 400-gal. centrifugal pump, located at the foot of one of our mine shafts became frozen. Upon investigation we found that the suction and discharge lines were also frozen for a distance of 120 ft. Our high-current transformer was placed on a truck and hauled to the mine where it was lowered in the shaft to the pump. Here it was set up and the secondary was connected to the suction and discharge line by means of 1,000,000 cm. cables. With a control resistance in the high-voltage circuit, the transformer was connected to one phase of the three-phase pump motor circuit, and the work of thawing out the pump and the 4-in. pipe line was started. The transformer was connected to deliver about 1,000 amperes, and the voltage applied to the high-voltage coils was regulated by means of a rheostat. Three hours from the time the transformer was connected to the power supply, both the pump and pipe lines were thawed out and again made ready for service. It can readily be seen that the cost of this work was very little compared with the cost of dismantling the pump and disconnecting pipe line, to say nothing about the possibility of breaking parts of the pump.

On many occasions, this same transformer has been used to thaw out

Transformer for High Currents

This transformer has two separate windings on both the high-voltage and low-voltage side. By proper connection it can be used on either 110- or 220-volt circuits, to deliver 1,000 or 2,000 amperes. Aside from being very useful in thawing out frozen pipe lines, it is frequently used for making high current tests. A transformer such as this can be used to thaw out frozen water lines around the mines and company houses and also to make high current tests on electrical equipment and circuits.

water service lines in some of the company's houses. With this transformer, our men have thawed out pipes in twenty different houses in less than five hours. To facilitate the work the transformer was hauled around on a truck and connected to a large lighting transformer.

F. F. MACWILLIAMS,
Power Department.
Pennsylvania Coal & Coke Corp.,
Cresson, Pa.

Renewal of Fuses Made Safer
On Transformer Circuits

While replacing the blown-out fuses on a mine-lighting transformer a man was injured and our company accordingly was prompted to devise a standard method for mounting and fusing such transformers.

We had previously issued instructions covering the replacing of fuses and had also designed our structures to be as safe as they could be made within reason. However, in the words of one of our inspectors, we felt we were obliged to make this work "unreasonably safe." As a result a complete new code of instructions was drafted and a new standard mounting adopted

The accompanying illustration shows how the transformer is mounted and how the connections are made from the high-voltage circuit through choke coils, fuses, and transformer to the secondary distributing lines. The most important safety feature is the West-

Table of Fuse Wires for 2,300-Volt Lighting Transformers

Kva. Capacity	Maximum Primary Amperes	Size of Aluminum Fuse Wire	Size of Copper Fuse Wire	Size of Iron Fuse Wire	Lead Fuse (Amp. Capacity)
1.5	1.4	40	40	35	2
3	2.8	36	38	31	3
5	4.6	33	35	28	5
7.5	6.8	31	33	26	7
10	9.2	29	31	24	10
15	13.6	27	29	22	15
25	22.8	24	26	19	25

inghouse Type "OD" safety fuse box and its position on the pole. It will be noticed that this equipment is located on the opposite side of the pole from the transformer. This arrangement makes it necessary for the person renewing a fuse to climb the pole or set up a ladder on the side of the pole where he will be safe.

The fuse is enclosed in a box and arranged in such a manner that the opening of the box breaks the electrical circuit. The fuse clips which hold the fuse are on the inside of the door and the fuse is in contact with the line circuit only when the door of the fuse box is closed. With this arrangement, when the use is replaced, it is inserted between two "dead" clips instead of two "live" ones which is the usual practice.

This new plan is not expensive because the fuse box serves the double purpose of a switch and a fuse compartment. Men at the mines have accepted the plan with much favor and look upon the work of renewing a fuse with little or no fear because they know they are not required to place

themselves in danger of coming in contact with any "live" parts.

To make certain that these transformers are not fused unreasonably above their full capacity, each mine electrician and electrical worker is supplied with a copy of the accompanying table. This table shows what size aluminum, copper or iron wire should be used to fuse a transformer. The last column shows the ampere rating of the lead fuse wire which also may be used. In the calculation of the table it will be noticed that a liberal overload has been allowed.

O. E. KENWORTHY.
Wilkes-Barre, Pa.

Composition of Insulation
For Mine Hangers

In answer to a request for information on the composition of the material used in mine suspensions, a large manufacturer of mine trolley equipment tells us the following:

The insulation used in the manufacture of mine hangers is a preparation whose constituents may be divided into three general classes: organic binders, inorganic binders and fillers.

The organic binders give the material its moldable properties, its moisture resistance, and its toughness, and are electrical insulators in themselves. Among these organic binders are phenol-formaldehyde compounds, shellacs, copals, and a number of other resins. In the manufacturing process these binders are very difficult to manipulate, and must be very carefully controlled, because they are extremely sensitive to heat.

The inorganic binders are generally fibrous in their nature; chief among these is asbestos. Great care must be exercised in the selection of a fiber, for there are many grades varying markedly in mechanical strength. The principal property desired of the fiber is length and toughness. The fibers are intimately mixed with organic binders, thus preventing them from functioning as a wick. The tensile strength of the compound depends a great deal upon the grade of fiber.

Fillers are usually mica, talc, very short asbestos, kieselguhr, or barium sulphate. These materials are all heat insulators, giving the compound a very high heat resistance. Like the asbestos, they are also very resistant to all acids, thus rendering the material particularly good for service in mines where damp acid conditions are so often found which make the insulation problem a very difficult one. These materials must be carefully and thoroughly mixed and moulded so that an insulating substance of uniform quality may be produced.

Lighting Transformer So Located on Transmission Line Pole
As to Be Safely and Easily Fused

The connections to the high-voltage wires are made through choke coils which protect the transformer from heavy surges or lightning disturbances. With the fuse boxes located on the opposite side of the pole from the transformer it is hardly possible for anyone to come in contact with the high-voltage wires or even with a ground connection.

Production And the Market

Flat Condition of Market for Bituminous Coal Causes Pronounced Tumble in Scale of Prices

Though the tendency of coal prices shows an even more marked downward course, consumers evince no disposition to recede from their recent policy of keeping out of the market and awaiting developments. In the absence of an impelling motive to buy, such as the menace of a nation-wide strike, buyers see no incentive to making commitments. The outcome of wage negotiations at Louisville, Baltimore and Philadelphia has been largely discounted by the agreement arrived at in Jacksonville last month.

The move of the Pennsylvania R.R. to lease the Norfolk & Western, followed quickly by efforts on the part of the New York Central, the Baltimore & Ohio and the Chesapeake & Ohio to gain control of the Virginian Ry., are fraught with interesting possibilities, not only on account of the immense coal traffic handled by the lines whose control is sought but because of the possible effect on the movement of West Virginia coal to New England. If the Pennsylvania and New York Central obtain control of the N. & W. and Virginian, developments in the movement of coal from the West Virginia field all rail as well as via Hampton Roads will be watched with more than ordinary interest.

Coal Age Index declined 2 points to 179, as of March 15, the corresponding average price being \$2.16. This compares with \$2.18 on March 8.

Midwest Price Cut Has Evanescent Effect

Price cuts in the Middle Western markets had an inspiring effect that was only fleeting, as they soon lapsed into a state of lackadaisical indifference. Scattered inquiries for contract coal have appeared, two railroads having placed half-million-ton contracts. The prevailing policy is to hold out, live off stockpiles and

wait for a lower market. Cold weather for a few days caused domestic business to perk up in southern Illinois and at St. Louis, but about half of the mines in the Williamson and Franklin County field are idle or will be by April 1.

Kentucky Markets Scrambled

As a result of wage cuts in eastern Kentucky screenings are offered in quantities at 75c. per ton, which has demoralized the market. Prices are weak also on steam coals and small prepared sizes. A possible strike in western Kentucky has caused some large consumers of pea and slack to place inquiries. Opening of lake business provides a ray of hope for some, though the absence of national labor or rail troubles is likely to cause buying to be slow.

Northwestern markets are practically dead, buying being from hand to mouth—by utilities to tide them over a water shortage. Some of the docks are working only three or four days a week, something hitherto unheard of at this time of year. Softness is the prevailing note in Ohio markets, the record of interchange of cars at Cincinnati showing a cluttering of the marts.

Dullness continues to pervade New England and the other seaboard markets as far south as Birmingham, consumers being well stocked and content to rely on their reserves for a while.

Production of bituminous coal during the week ended March 8 amounted to 9,596,000 net tons, according to the report of the Geological Survey, a decline of 1,104,000 tons compared with the previous week. Output of anthracite increased slightly, 1,882,000 tons being produced, compared with 1,866,000 tons in the previous week.

Midwest Cuts Prices

The flat market on all coals compelled a change March 13 in the southern Illinois scale of prices. Franklin County association operators dropped lump and egg from \$3.75 and \$3.50 to \$3; No. 1 nut to \$2.75, and No. 2 to \$2.50. Saline County producers, next door to Franklin County, said they would try to maintain the same circular, though they normally are 25c. under it. At the end of the week this cut had shown only a little inspiring effect on the market. Nothing seems to wake it. Spring weather is here after a little business during several late snows, and domestic coals are all bought in smallest quantities.

A few inquiries for contract coal are circulating the trade at Chicago from scattering railroads and industries of various sorts, but they are not numerous. The general policy still is to hold out, live on storage piles and wait for a lower market. At least two half-million ton railroad contracts in the Midwest have been signed for southern Illinois at \$2.50, however.

Steam business is by no means keen, even though production in Illinois and Indiana keeps dropping and the volume of screenings gets smaller and smaller. Southern Illinois producers are making a stout effort to push the

price of screenings to \$2.25, but about \$2.10 is the top thus far, with most of the trading at \$1.90@\$. Indiana Fourth Vein screenings are at the same level. Central Illinois, with practically no volume but with a short haul to Chicago's great steam market, runs along at \$1.75@ \$1.80.

Cold weather for a few days in Southern Illinois stimulated activity in domestic sizes, principally lump, although egg and nut are heavy. Practically all mines have unbilled coal on track. Steam shows a little activity, but it is not progressing as might be expected, although with warmer weather there is every indication that it will advance. Railroad tonnage is reported light. Cars are plentiful and are moving well and mines are getting from two to four days a week, as a rule. Several mines have been idle and some have suspended indefinitely. It is estimated that one-half of the mines in the Williamson and Franklin County field are idle or will be by April 1—indefinitely.

St. Louis Does Some Business

Cool weather caused some domestic activity and dealers are pretty well loaded up with small orders on the cheaper grades. High grade is not popular and anthracite and smokeless are moving slowly, but coke shows up somewhat

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924	1923
Index	March 17 179	March 19 263
Weighted average price	March 10 \$2.18	March 3 \$3.19
	March 3 \$2.21	

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

better. Local steam is fairly active in carloads but wagon trade is beginning to ease up. Country domestic has shown considerable activity the past week, for cheaper grades principally. A little inquiry is made for anthracite chestnut. Country steam is not good. There is no change in retail prices.

Kentucky Prices Drop Too

Business over the past few days in Louisville has been unsatisfactory. Wage reduction in some parts of the eastern Kentucky field has resulted in screenings being offered in quantities at 75c. a ton, and mine run at \$1.15@\$1.35 a ton, which has demoralized the market. Prices are generally weaker on steam coals and small sizes of prepared, and it is asserted that there isn't much coal commanding over \$3 a ton at the most.

In view of the possibility of a strike in western Kentucky a few of the large consumers of pea and slack size screenings have been placing inquiries for supplies. Opening of lake business next month will aid the eastern Kentucky section, but without any pending national strikes or railroad troubles buying will be slow.

Lack of production of prepared sizes in western Kentucky is resulting in a firm market on screenings and rela-

tively light offerings. The present market is quoted at \$1.25@\$1.40, and is likely to go up unless some lump business is offered. Lump is \$2.75@\$3 and egg, \$2.50@\$2.75. Some mines have no screenings to sell and are only quoting screenings where the buyer will take prepared. Some operators are reported to be installing crushers, in order to crush mine run or nut and slack into pea and slack, to take care of the steam demand for fine coal. Western Kentucky is expected to go non-union after April 1, except possibly a region in Muhlenberg County where unionism is stronger.

Northwest Trade Is Flat

The coal market at Duluth is more than quiet. It is practically dead, with the exception of a few orders from the public-utility companies, which are buying often, from hand to mouth, because of the shortage of water flow for hydraulic plants. It begins to look as if the public-utility companies will be the savers of the day, as little snow is on the ground and their unusual wants may cause the docks to get rid of their surplus supplies. To illustrate the quietude, some of the docks are working only three or four days in the week. This is practically unheard of at this time of the year.

Prices went down and up during the week. The Superior Coal & Dock Co., which has discontinued because its parent concern in the East, the Maynard Coal Co., is in the hands of a receiver, lowered the price of Hocking 25c. to \$5.75, and other companies followed suit. This was done, of course, in an effort to clear stocks. The dock closed, however, and prices went back to list.

Shipments of the docks during February ran slightly higher than expectations, with 17,188 cars reported. This was principally railroad coal that was hauled to depots for use in case of a cold snap. In January 25,984 cars went out and in February last year 13,969 cars. Dock men expect poor shipments this month.

The demand for coke has fallen off, as also has that for hard coal. Mild weather is the cause. However, the briquet business has picked up some.

All is quiet in coal circles at Milwaukee pending the readjustment downward of soft-coal prices. Dockmen will have to follow Western coal down if they expect to reduce their unusually large spring surplus before new coal begins to arrive.

Kansas Prices Down 50 Cents

The price of Kansas lump and nut was cut 50c. a ton March 10. Present quotations are \$4.50 for lump and \$4 for nut. Mine run is quoted generally at \$3.25, although it still is listed by some operators at \$3.50. Screenings are \$2.50. The slash on lump and nut was due chiefly to the nearness of the end of the season. The accumulation of "no bills" of the two sizes was increasing, although operating time had been cut to three days a week. The reduction, coupled with a return of cold weather at the same time, has reduced the surplus, but the relief is expected to be of short duration.

The coal market in Colorado was fairly busy during the past week. Mines worked a little better than half time. Seasonable weather has again set in throughout the regions where this coal is marketed and with the recent extreme cut, business is expected to pick up.

Utah operators report business quiet. Mines are working less than two days a week. The demand for lump is falling off although retailers have been enjoying a little business during the past week as result of a cold snap. Industrials and larger consumers continue to clamor for slack. Prices are unchanged and labor conditions are settled.

Ohio Markets Soft from Oversupply

J. A. Morris, district manager for the American Railway Association at Cincinnati reports that 12,453 cars of coal interchanged at Cincinnati last week, an increase of 223 over the previous week and an increase of 2,411 compared with same week last year. This is the heaviest interchange of coal on record in this terminal, except for one week in the month of June, 1922, when 13,825 cars of coal were interchanged, but this included 2,410 cars of coal en route to the lakes. No better means of explaining the softness and shallowness of conditions here could be found.

There is practically no demand for any particular kind of coal. From the low volatile to the lowliest of any "black

dirt" offerings neither price nor energy seems to move sales. There are still a large number of rejections and those operators who have been turning out tonnage persist in cluttering the immediate markets by shooting their free tonnage on consignment.

Dullness characterizes the Columbus market. Domestic business is exceedingly spotty and little activity from that source is now expected, as this trade is now purely a weather proposition and dealers are loath to increase stocks. The fancy grades, such as Pocahontas and other smokeless grades are selling fairly well, although prices are showing some softness. Steam trade is almost at a standstill, as the larger consumers are using reserves accumulated prior to the wage settlement. They are gradually working to a normal basis. There has been considerable distress coal in steam sizes and these were sacrificed at rather low prices. Utilities are not buying to any extent and railroads are taking only their usual requirements. Screenings have been rather dull, as stocks have been heavy and prices in some instances went very low. Production in all Ohio fields has fallen to about 20 per cent of capacity as a result of the falling off in demand. Some stir is shown in the lake trade, one large Ohio producer having started to load boats in the Toledo harbor.

Hesitancy continues to dominate the Cleveland coal market. Consumers are not purchasing, but are awaiting further depletion of coal put in prior to mid-February, when all apprehension was removed in so far as mining cessation was concerned. Despite the dull market, spot prices are holding firm at recent levels, with the slight exception of $\frac{3}{4}$ -in. lump, some sales of which are reported at \$1.90 as compared with a previous low of \$2. Mining operations have slowed down, production in the eastern Ohio field during week ended March 8 being 324,000 tons, the lowest of any full week's operations, excepting the holidays, in eleven months.

Production in the Pittsburgh district has been declining slightly. The full force of the competitive condition between the district and various non-union districts will not be felt until after April 1, when contracts expire. Nothing definite has developed as to contracts for the new coal year; there does not seem to have been enough actual negotiating to develop actual prices on contract. In the spot market prices are unchanged except that steam slack has continued to decline, being forced for sale on account of heavy shipments of domestic lump, while some consumers have stocks of slack they are liquidating.

No improvement is shown at Buffalo. Consumption is pretty good and so is the general business feeling, but output exceeds requirements.

New England Market Drags

In New England the market drags along with no bright spots anywhere. Even with the approach of April, buyers show almost no interest in prices, either spot or for season delivery. The few consumers who expect to be in the market later on are only keeping in touch with current quotations to measure the possible spring decline when conditions settle down for the long pull through the summer months.

At Hampton Roads there is no appreciable change. Navy standard grades of Pocahontas and New River are available in any quantity desired, and the spot price per gross ton f.o.b. vessel ranges from \$4.60 to \$4.75. Those agencies with strong Western connections continue to move a fair

proportion of their output in that direction at slightly better than \$4.75 at Hampton Roads. Others, however, with less Western business are inclined to take from 10 to 15c. less in order to keep coal moving to the piers. At this end there is constant pressure to sell coal against arrivals, and for that reason \$5.90 per gross ton on cars, Boston, is about the highest figure obtainable from any except small users. At Providence and at Portland, due to better local conditions, the on-car basis is somewhat higher.

All-rail there is next to nothing doing. What tonnage is being placed is on small requirements, and the active shippers are busy combing over every possible prospect.

No Ardor in Seaboard Markets

Little enthusiasm is in evidence in the soft-coal market at New York. The general market is quiet, only the better grades and some individual coals moving easily. Some contracts have been renewed at 25c. to 50c. above present spot prices, but many consumers who in former years have had contracts are going to take chances with the open market. Demand in the spot market is slow and prices show comparatively no change. Many consumers have from sixty to ninety days' reserves on hand.

The consumer is sitting pretty in the Philadelphia market, everything seeming to be in his favor. He now knows that he can get coal whenever he wants it, and he is coming close to the point where he does not want much. Prices hold firm. The producers seem to have said "this is bottom" so long now, that it actually seems to be true, and no sign of slackening demand, which occasionally crops up, has any adverse effect on spot prices.

The Baltimore trade is encouraged by a stronger line of inquiry both for spot and contract business after April 1, and price quotations, while still weak, are the best for some time past. The fact that little or no trouble is anticipated from labor sources in the mining regions is probably the only thing that has checked a sharp advance of the market.

Anthracite Moving Only for Actual Needs

Activity in the anthracite domestic coal market at New York is limited to the actual needs of consumers. It is however, sufficient to take care of shipments to this tide-water. There have been some offerings at tidewater of loaded boats of the larger sizes which have been let go at slightly less than current spot prices, but such sales have been few. Egg coal is slowly gaining in strength, demand is better and more is being sold at the average price than at a low figure. Stove and chestnut continue in good demand, while pea coal is moving slowly. Barley and birdseye are in good call. Buckwheat and rice are not active and can be had below company schedule. Normal March weather in Philadelphia has served to make some business for the retailer, but the consumer is buying as little coal as possible, being firmly convinced that he is going to get cheaper coal after April 1, and quite a few dealers hold a like opinion.

Foreign Market And Export News

British Collieries Booked to Mid-April; Output Declines Again

The Welsh coal market is unsettled as an aftermath of the dock strike. While stocks lasted the market was unaffected, but the subsequent disorganization is very evident. Dealers report difficulty in effecting arrangements for new business because all collieries are heavily booked with orders to the middle of April. Dealers are much in arrears with their deliveries and find it impossible to overtake orders with the two-shift working system.

The domestic demands continue very large and foreign buyers are reported to be placing substantial orders in the United States owing to their inability to obtain requirements in the British market even at enhanced prices. Foreign buyers in some cases are accumulating stocks against an expected strike of miners. The anthracite market is firm and steady, and all the best grades are well booked. Demand from France and Italy is good.

Output of British collieries during the week ended March 1, a cable dispatch to *Coal Age* states, was 5,702,000 tons, according to the official reports. This compares with 5,802,000 tons in the week ended Feb. 23.

In the Newcastle market prices have slightly appreciated and show a tendency to harden. Most of the collieries are well sold for several weeks. Inquiry from Germany shows a tendency to fall off.

Hampton Roads Discerns Brighter Outlook

Business is dull on spot at Hampton Roads but movement is fairly heavy on contracts, particularly to South American ports. Prices are dropping, which is attributed by shippers to the fact that no untoward incidents impend in the coal trade to disrupt the market.

Coastwise business is fairly good, as is the bunker trade, but dumpings have fallen off somewhat. Several inquiries

which may lead to big contracts later are reported by shippers, but as a whole the tone of the market is dull. The outlook is reported by shippers as brighter, however, with the expectation that April 1, the annual contract period, will see buyers coming into the market substantially.

French Coal in Brisk Demand; Domestic Consumption Heavy

Demand for French fuels continues to be the feature of the coal market in France, consumers desiring to avoid the high prices prevailing for British coal. Consumption of domestic fuel is heavy, due to the continued cold weather.

Price reduction is not being uniformly applied, certain mines in the Loire basin with difficult workings having lowered their prices by 1, 2 and 3 fr., according to grade. As there was no increase last January in the Lorraine and Sarre coal fields, prices there are unchanged, but a reduction is expected soon in the latter field. These price changes come at a time when miners are about to ask again for higher wages, due to the increased cost of living.

Shipments of Sarre coal to France could reach an average of 50,000 to 60,000 tons a day but for a scarcity of trucks. Imports of British coal have fallen off considerably. The strikes in Great Britain had no direct influence on the French market, as the demand for imported house coals has been lower.

Deliveries of indemnity fuels continue at about the rate for the last two months. During February the French metallurgical industry received a daily average of nearly 11,000 tons of coke. The government has informed the Office des Houillères Sinistrées that the price for German coke will be maintained at 143.50 fr. (delivered at the frontier) for March.

Nearly 18,500,000 fr. was collected

on the coal tax in the Ruhr during the last ten days in February, 6,000,000 fr. of this covering arrears in taxes. The output of several of the most important mines in the area, belonging to the Thyssen, Stinnes, Krupp and other groups, now is in excess of the 1922 output by from 10 to 27 per cent.

Supreme Court Advances Appeal In Car-Distribution Case

Motion to advance the appeal of the federal government from the decision of the Southern West Virginia District Court in favor of the New River Co. and various other coal mining companies setting aside the Interstate Commerce Commission order regarding car distribution to mines served by more than one carrier was granted by the U. S. Supreme Court March 17 and the case was set for argument April 21.

In its order the Interstate Commerce Commission on Dec. 11, 1922, directed that mines served by more than one carrier should file copies of car requisitions with the agent of each carrier and that the combined requisitions must not exceed the gross daily rating of the mines. The district court, with three judges presiding, voted two to one, granting a permanent injunction to the mine companies and setting up a system of coal-car distribution which differs from that laid down by the Interstate Commerce Commission. The government appealed, and filed a motion to expedite the case, which motion has been granted.

Propose Advance in Coke Rates

The Coal, Coke & Iron Ore Committee, Central Freight Association Territory, announces a hearing in Room 606, Chamber of Commerce Building, Pittsburgh, Pa., Thursday, March 27, 1924, at 10:00 a.m., on the following proposed changes in rates on coke (except petroleum, creosote and tar or pitch coke), coke breeze, coke dust and coke screenings, carloads, from ovens on Louisville & Nashville and Interstate Roads in Virginia, Kentucky and Tennessee, and from ovens on the C. N. O. & T. P. Ry. (Southern Ry.), to Cincinnati, Ohio, Latonia, Covington and Newport, Ky., rate to be advanced from \$2.59 per net ton to \$2.90 per net ton; to Louisville, Ky.; Jeffersonville and New Albany, Ind., rate to be advanced from \$2.37 per net ton to \$2.65 per net ton. These proposed advances are intended to restore parity of rates with those from C. & O., N. & W. and Connellsville (Pa.) districts which was disturbed by the decision in ICC-Ex Parte 74.

Hearing on Rate Advance

The Coal, Coke & Iron Ore Committee, Central Freight Association Territory, announces that a hearing will be held in Room 606, Chamber of Commerce Building, Pittsburgh, Pa., Thursday, March 27, 1924, at 10 a.m., on the following proposed changes in rates on bituminous coal, carloads: From mines on B. & O. R.R. in No. 8 (Ohio) District to Peoria, Ohio, via New York Central R.R. (Ohio Central Lines); from mines on B. & O., D. T. & I., N. & W. and Hocking Valley roads, in Jackson County (Ohio) District to Peoria, via

New York Central R.R. (Ohio Central Lines), and from mines on Hocking Valley road to Raymonds, Lunda and West Mansfield, Ohio, via New York Central R.R. (Ohio Central Lines); rates to be advanced 6c. per ton, to \$1.89, to remove long- and short-haul clause departures. Rates from Clarion, Dundas, Elfork, Hawks, Minerton, McArthur, Oretton, Orland, Radcliff and Vinton, Ohio, on the Hocking Valley Ry., to Peoria, Raymonds, Lunda and West Mansfield, Ohio, to remain as at present, i.e., \$1.64 per net ton.

C. & O. Breaks Loading Record

The Chesapeake & Ohio established a new high record for coal loading in February, 18,011 carloads being moved in the week ended March 1. The previous high record was 17,742 cars, loaded during the week ending Sept. 1, 1923. Although February was a short month, loadings for the month totaled 68,551 cars.

Association Activities

The the annual meeting of the Upper Potomac Coal Association, held in Cumberland, the following officers were elected: President, T. M. Dodson of Bethlehem, Pa. (re-elected); Vice-President, R. Marsh Dean, of Elk Garden, W. Va., to succeed J. A. Brown of Frostburg, Md.; Treasurer, R. A. Smith, of Blaine, W. Va. (re-elected); Secretary, J. F. Palmer, of Cumberland, Md. (re-elected). Three new directors were chosen to serve on the board for the ensuing three years. They are Douglas Gorman, of Baltimore, Md.; S. D. Brady, of Fairmont, W. Va. and J. G. Emmons, of Philadelphia, Pa. The board of directors held its meeting prior to that of the membership as a whole and reviewed the year's activities and transacted routine business. The meeting of the association proper was held in the ball room of the Fort Cumberland Hotel, the tonnage of the Upper Potomac, western Maryland and western Pennsylvania fields being well represented. The principal speaker at the meeting was Harry L. Gandy, executive secretary of the National Coal Association. Mr. Gandy addressed himself to the legislation situation at Washington and discussed the benefits of association activities and co-operation between coal operators. Following his address members were given an opportunity to discuss questions of interest to the industry.

The Fayette-Greene Coal Producers Association held an important meeting at the Uniontown Country Club March 10, when forty-five coal and coke operators with interests in the two counties were present. Charles O'Neil, secretary-treasurer of The Central Pennsylvania Coal Producers Association, of Pittsburgh, was the speaker of the evening and he brought to the Fayette-Greene operators a message of striking importance. There also were several impromptu talks by members of the Association. G. Carl Areford, president, presided.

The Hampton Roads Coal Association, composed of representatives of practically all coal agencies at Norfolk, established to create better fellowship and improve operating conditions, has been formally organized with a board of directors which has been instructed to choose officers from its own members. The board will elect a president, vice-president, secretary and treasurer. The board members are Lewis Littlepage, Smokeless Fuel Co.; Clayton Wigg, Houston Coal Co.; T. M. Bailey, Virginia Smokeless Coal Co.; T. R. Licklider, Trans-Ocean Coal & Export Co., and Chester B. Koontz, Willard-Sutherland Coal Co.

Obituary

William Andrew Windatt, president of the Windatt Coal Co. of Winnipeg, Man., died on March 5 at the age of 63 years. He was born at Bowmanville, Ont., and came West when a young man. After being for some years engaged in the coal and banking business in Moose Jaw, Port Arthur and Portage la Prairie he settled in Winnipeg in the early 90's and established the business which bears his name. Mr. Windatt also was managing director of the Home Investment Co., and had other large interests including the Foothills Collieries, Ltd. Mr. Windatt had been an invalid for some time and his death was not unexpected. He leaves a widow, two sons and three daughters.

John T. Werry, of Johnstown, died at his home there on March 12, following a long illness from arterio sclerosis. He was born in Cornwall, England, Nov. 11, 1848. He came to America when 18 years of age and settled in Johnstown immediately and entered the coal business, spending most of his time with the Haws Manufacturing Co. He began his work with Andrew J. Haws and for a long time was foreman of the mines. He retired three years ago.

James Meehan, well known in the coal-mining industry in central Pennsylvania, died March 10 at his home in Morrellville (Johnstown) in his 69th year. At the age of 17 he took a job in the mines at Blossburg, Tioga County. It was while he was working in the vicinity of Houtzdale that he received his mine foreman certificate from the same board that examined John Lochrie and "Jack" Hughes, both now in Windber. In 1903 he took charge of Mine No. 35 for the Berwind-White Coal Mining Co., at Windber, and was later associated with the Hastings-Beaver-Spangler interests at Hastings, Spangler and Bakerton. He is survived by two sons, Harry J. Meehan, of Westmont, a coal operator in central and western Pennsylvania, and James A., also of Westmont, and three daughters, all of Johnstown. Burial was at Carrolltown.

William G. Barnhardt, a prominent coal dealer of Kitchener, Ont., died a few days ago of pleuro-pneumonia. He was 54 years of age and was formerly assistant fuel controller.

Coming Meetings

New England Coal Dealers' Association. Annual meeting March 20-21, Boston, Mass. President, W. A. Clark, Boston, Mass.

Association of Iron and Steel Electrical Engineers. Fuel Saving Conference, April 2 and 3, William Penn Hotel, Pittsburgh, Pa. Secretary, J. F. Kelly, Empire Bldg., Pittsburgh, Pa.

Canadian Retail Coal Association. Annual meeting, April 3 and 4, King Edward Hotel, Toronto, Ont., Can. Secretary, B. A. Caspell, Brantford, Can.

American Institute of Electrical Engineers. Spring convention, April 7-10, Birmingham, Ala. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

American Welding Society. Annual meeting, April 22-24, Engineering Societies Building, 33 West 39th St., New York City. Secretary, W. M. Kelly, 33 West 39th St., New York City.

National Exposition of Coal Mining Equipment and Machinery of the American Mining Congress. May 12-17, Cincinnati, in conjunction with the annual meeting of the National Coal Association.

National Coal Association. Annual meeting May 14-16, Cincinnati, Ohio. Executive Secretary, H. L. Gandy, Southern Building, Washington, D. C.

International Railway Fuel Association. Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

The American Society of Mechanical Engineers. Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

The National Foreign Trade Convention. June 4-6, Boston, Mass. Secretary, O. K. Davis, 1 Hanover Square, New York City.

News Items From Field and Trade

ALABAMA

The Bessemer Coal, Iron & Land Co. has acquired an interest in the Nashville Bridge Co. H. L. Badham, president of the former company, will be added to the directorate of the bridge company, which is about a million dollar corporation, with a subsidiary plant in Bessemer.

The state has leased the Belle Ellen Mines of the Bessemer Coal, Iron & Land Co. on a royalty basis of 35c. per ton on coal removed, the coal to be sold by the state. The object of the new agreement is to get away from the convict leasing system which has been in vogue in the state for many years whereby several of the larger mining companies have been leasing the state and county convicts and employing them in the operation of their mines, and is in the nature of an experiment of several plans which have been under consideration. It is probable that similar contracts will be entered into with the other companies employing convict labor in the coal fields.

The state has leased the Flat Top mine of the Sloss-Sheffield Steel & Iron Co. and will employ its convicts in the operation, furnishing washed coal in cars at \$1.30 per net ton. The tonnage tax will be paid by the owners of the mine. Flat Top mine is one of the largest coal producers in the Birmingham district, the average output being about 2,200 tons daily. Convicts have been employed in this mine since it was opened up, about twenty-two years ago, the company leasing the prisoners at a stipulated rate per month. The new agreement is to take effect July 1, 1924, and is intended as an abolition of the leasing system, against which a bitter campaign has been waged in the state for the past year or more. The product of the mine does not enter the commercial market being coked in the byproduct plant of the company.

In line with its policy of promoting first-aid and accident-prevention work among its employees, the DeBardeleben Coal Corporation will stage a first-aid contest at Jasper, Ala., March 21, according to announcement of Milton H. Fies, operating vice president of the company. Only employees of the corporation will enter the contests, every mining camp being represented by one or more teams.

Priestly Toulmin, Herbert Tutwiler and associates, of Birmingham, are developing a new mine at Trafford, Jefferson County. Production of around 800 tons per day is contemplated. The operation will be located on the Louisville & Nashville R.R. A washery is being constructed.

The Stith Coal Co. has about completed its 400-ft. shaft at America Junction, Walker County, to reach the Mary Lee seam of coal and is now preparing to install a large washery plant.

INDIANA

Clem J. Richards, receiver for the Sugar Valley Coal Co., of Terre Haute, has been granted permission in Superior Court to sell all the property of the concern.

P. F. Bolinger, cashier of the First National Bank of Shelburn, was named receiver for the Star City Coal Mining Corporation, Star City, by Judge Walter F. Wood. The receivership was declared on a petition of the National City Bank of Indianapolis, which holds a note for \$18,000 against the company.

KENTUCKY

Several mines in the area of the Kentucky-Tennessee Coal Operators Association in the Hazard and Harlan fields of southeastern Kentucky which were closed down because of inability to agree on wage scales with the representatives of the United Mine Workers, are resuming work. It seems that the men were promised strike benefits, but these have failed to materialize.

Under date of March 8, a press dispatch from Knoxville, Tenn., stated that coal from the Stony Fork Coal Co., L. C. Gunter, president, would move from the

Kentucky mines to the Compressed Coal Co., Savannah, Ga., for use in manufacturing briquets, which will be one of the principal products of the latter company. The report stated that James Imbrie, New York, was associated with Mr. Gunter in the Compressed Coal Co., a \$1,000,000 corporation, formed in West Virginia. Mr. Gunter was formerly president of the Southern Appalachian Coal Operators' Association and is president of the Knoxville & Carolina R.R.

A bill by Senator Tabor has been passed by both houses and signed by Gov. Fields, which will make script, checks, tokens, etc., issued by coal mining companies and other employers, redeemable at face value, and also transferable. The bill was passed in 1922, but was lost before being recorded, and never was signed.

An effort to force the resignation of Lonnie Jackson, president of District 23, United Mine Workers from the office of Mayor of Central City, failed on the floor of the biennial convention at that town, March 6, the vote being 92 to 21 in favor of his continuing as mayor of the city. A small minority endeavored to show that his duties as mayor were interfering with his work as president of the district union.

Senator Hiram Brock of Harlan, has put a bill through the Kentucky Senate to regulate type of containers used, and amount of explosives which can be taken into Kentucky coal mines at any one time. The bill passed by a 20 to 14 vote.

The Pittsburgh Coal Co., Baskett, of which Alexander Blair is president has changed its name to the Race Creek Coal Co., Inc. The management remains the same.

The Hazard Fuel Co. of Lexington, capital \$50,000, has been chartered by T. F. McConnell, W. J. Raibould and Asa Ewen.

T. C. Miller on March 15 became superintendent with the Elkhorn Coal Corporation at Jackhorn, Letcher County.

MISSOURI

About 15 cars of coal per day are replaced by electric power to be furnished on a contract just signed by the Pittsburgh Plate Glass Co. for its Crystal City plant from the new gigantic Cahokia power plant of the Union Electric Light & Power Co. across the river from St. Louis. The contract calls for total payments of \$600,000 a year for 10 years and is the first big contract signed for the new Cahokia station. The glass company will continue to use coal for its gas producers and yard locomotives.

NEW YORK

A new issue of \$2,500,000 Central Coal & Coke Co. first mortgage 6½ per cent sinking fund gold bonds, closed mortgage, series B and C, at 98, to yield about 6.65 per cent, is being offered. The bonds are dated March 1, 1924, and are due March 1, 1944. The Central Coal & Coke Co. owns and operates extensive timber and coal properties in Oregon, Louisiana, Texas, Missouri, Kansas, Oklahoma and Wyoming. The bonds are the joint and several obligations of the Central Coal & Coke Co. and the Delta Land & Timber Co., a wholly owned subsidiary. Net operating earnings of the Central Coal & Coke Co. and its subsidiaries, not including Oregon-American Lumber Co., for the seven-year period ended Dec. 31, 1923, averaged \$1,033,515.40 or more than 2½ times the maximum annual interest requirements on all outstanding first-mortgage bonds of the company.

The Sunday Creek Coal Co., Columbus, Ohio, announces the opening of a sales office at 872-74-76 Ellicott Square, Buffalo, in charge of J. Fred Morlock.

The Board of Directors of the Lehigh Valley Coal Sales Co. has declared a dividend of \$2 per share payable to stockholders on April 1.

The Island Creek Coal Co., of Boston, has declared an extra dividend of \$1 on the common stock, the regular quarterly dividends of \$2 on the common and \$1.50 on the preferred, payable April 1 to stock of record March 26.

OHIO

The Essex Coal Co., of Columbus, is installing oil-burning boilers at three of its operations in the Hocking Valley field to operate electrical plants. The mines being thus equipped are the Hocking Valley Mining Co., at Hocking; the Kimberley Mining Co., at Nelsonville, and the Ohio Mining Co., at Jackson. At each place two 300-hp. oil-burning boilers are being installed which will operate generators capable of generating about 700 kw. The company is taking advantage of the slack demand in order to make the improvements, which are expected to be completed in a month.

Richard Osborne, general manager for the Borderland Coal Sales Co. for the past year, with headquarters in Cincinnati, has resigned and has opened an office for the Mid-West Coal Co., of Cario, Ill., which will be located in the Union Trust Building, Cincinnati.

The Columbus office of the Pittsburgh Coal Co. started lake shipments late last week from its Ohio and Kentucky mines for transshipment on bottoms tied up in the Toledo harbor. This is expected to relieve the situation to a certain extent as a considerable loading of bottoms will be made to wait for the official opening of the lake season.

W. T. Richardson, vice president of the Universal Coal Co. of Price Hill, W. Va., who directed the firm's Western selling office in Cincinnati, has resigned and has been appointed manager of the Cincinnati office of Dexter & Carpenter, Inc.

The J. R. Fitzer Coal Co., Columbus, which has offices in the Citizens' Trust Bldg., is being operated by John Fitzer, son of the late J. R. Fitzer, under the same name. This company has two very important selling connections.

The Kanawha & Ohio Coal Co., Columbus, of which Sheldon Smith is at the head, has moved its offices from the Arcade Building to the Douglass Building.

The General Electric Co. moved the headquarters of its East Central district from Cincinnati to Cleveland on March 1, according to a recent announcement. In the latter city, combined with the local Cleveland office of the company, it will be located in the new Union Trust Co. building.

OKLAHOMA

The Acme Coal & Coke Co. will build five miles of railway tracks at its strip pit 2½ miles east of Stigler. It now operates three miles of track. This company shipped 123 cars of coal in January, the largest monthly shipment it has made since it began operations in 1920. The product was shipped into eleven states.

PENNSYLVANIA

The Hudson Coal Co., which owns extensive tracts of anthracite land near Mechanicsville, Schuylkill County, has erected drills on Salem Hill, Port Carbon, Schuylkill County, with a view of locating definitely some of the big seams known to exist in that vicinity. It is expected that a colliery employing about 800 men will be erected by that company on the site of the proposed workings and homes and other buildings constructed for the workmen and their families. Many coal companies, operating in Scranton and Wilkes-Barre, are rapidly invading the Schuylkill fields. Incidentally with the announcement of the Hudson Coal Co. the Peach Mountain slope in Schuylkill County, after an idleness of seventy-five years, is again in operation. The independent operators in charge of the colliery found that they can strike a large body of coal containing hundreds of thousands of tons through this slope and had it opened at a great expense. The Peach Mountain slope was one of the many operations abandoned in the Schuylkill region when it was found cheaper to mine the beds in the vicinity of Scranton and Wilkes-Barre.

The merger of the Cosgrove-Meehan Coal Co., located in Johnstown, has received the approval of the state. The capital stock of the merged interests is given as \$315,000. J. E. Graham, of Johnstown, is treasurer. Companies entering the merger are the Homer City Coal Co., Purity Coal Co. and the Grazier Coal Mining Co.

Coal production in the Tenth bituminous district, which includes the mines in Blair and a portion of Cambria county, was 3,230,593 tons in 1923, according to the report of Mine Inspector Joseph Williams, of Altoona.

Approximately 15,000,000 tons of coal, or an increase of 50 per cent over the previous year, was produced in the **Cambria County region during 1923**, according to the annual reports of the state mine inspectors of the four districts of which Cambria county is a part. The number of tons produced per fatal accident in the Sixth district was double that of the previous year, according to State Inspector Thomas D. Williams. The Bethlehem Mines Corporation, a subsidiary of the Bethlehem Steel Corporation, produced 2,101,272 tons, or more than 40 per cent of the coal mined in the Sixth district, in which it is located. An increase of approximately 62½ per cent in coal production over the 1922 figures was recorded in the Thirteenth district, Inspector John I. Thomas reported. Few accidents marred this production record. A total of 4,753,805 tons of coal was produced last year in the Thirtieth district, of which Charles H. Crocker is inspector. This district comprises mines in Cambria, Indiana and Westmoreland counties. Of the amount, 1,514,487 tons was mined in Cambria County.

River coal, or anthracite washed down stream from the mines, valued at \$605,822 was recovered in 1923 from the Susquehanna, Schuylkill and other rivers, according to reports made to Auditor General Samuel S. Lewis for taxing purposes. The coal had an average value of \$1.27 a ton. Sixty corporations, firms and individuals have made reports and they will pay a state tax aggregating \$9,087.33.

The State Supreme Court has affirmed the judgment of the Greene County Common Pleas Court in the case of the Shannopin Coal Co., which appealed from the triennial assessment for 1922, 1923 and 1924. The lower court reduced the valuation. The County Commissioners then appealed the case to the Supreme Court and it was agreed that all appeals taken from assessments of coal lands should abide by the final decree of the higher court in the Shannopin case, and that assessments made be reduced by a like percentage in case the reduction made by the Greene County court should be sustained.

The anthracite producing companies in their reports of 1923, made to Auditor General Samuel S. Lewis, for state coal-tax purposes, indicate a total tax due considerably in excess of the estimated return and \$3,500,000 more than was reported for the year 1922. "An increase in state revenues is shown by the indicated yield from the anthracite coal tax for 1923," Auditor General Lewis said. **The tax reported for 1923 by the anthracite coal operators aggregates \$7,273,788.** A feature of the tax shown by the reports, the period for the filing of which expired recently, is that ten coal companies report eighty per cent of the tax. Two companies reported a tax of nearly \$1,000,000, each, for the year.

The following bituminous coal companies, which will mine and manufacture coke and by-products and all of which have their home offices at Ligonier, were incorporated recently at the State Department at Harrisburg: **Ligonier Diamond Coal Co.**, No. 2, capital stock, \$52,000; incorporators, John Seger, W. J. Seger and Joshua Vogeles. **Seger Brothers Co.**, Ligonier, \$370,000; incorporators, John Seger, Joshua Vogeles and H. E. Behrhorst. **St. Clair Fuel Co.**, \$136,000; incorporators, John Seger, Mayme Vogeles and Dora D. Seger. **Seger Brothers Coal Co.**, \$710,000; incorporators, John Seger, Joshua Vogeles and Jane Crann. **Vogeles Coal Co.**, \$35,000; incorporators, John Seger, Mayme Vogeles and H. E. Behrhorst. John Seger, Ligonier, is treasurer of all of the companies.

TENNESSEE

By court decree of Feb. 23, at Nashville, the property operating the past seven months as the Old Hickory Powder Plant Receivers has been restored to the **Nashville Industrial Corporation**.

UTAH

It is planned to provide the first unit of the blast furnace of the **Columbia Steel Corporation** near Provo, in Utah County, with ten cars of iron ore, twenty-five cars of coal, and five cars of limenock a day. The plant will be in operation in a few weeks.

L. F. Rains, president of the Carbon Fuel Co., of Salt Lake City, has been appointed to the production committee of the U. S. Chamber of Commerce.

The capital stock of the **Mutual Coal Co.** has been increased from \$500,000 to \$800,000. **The company had not lost a day due to poor market conditions since July 1.**

VIRGINIA

The Amherst Coal Co. has opened an agency at Norfolk with H. M. Fadeley, formerly with the Low Volatile Consolidated Coal Co., in charge. H. W. Moore, formerly with the Port Dearborn Coal Co. at Norfolk, also is in the new agency.

E. H. Jarvis, formerly with the Low Volatile Consolidated Coal Co., has become associated with the Smokeless Fuel Co. at Norfolk.

W. R. Moore, of the Houston Coal Co., Norfolk, has gone to Richmond to take a position with the Raleigh Smokeless Fuel Co. **J. B. McClure**, of the Beckley, (W. Va.) office of the latter concern, has gone to the Norfolk office of his company.

WEST VIRGINIA

The No. 2 mine of the **New River & Pocahontas Coal Co.**, on Laurel Creek, in the New River field, which had been in idleness for some time, resumed operations during the first week of March. The company is having 100 new mine cars constructed. This company has not reduced wages, paying the same scale which has been in force for the past two years.

The Supreme Court of West Virginia has held in the case of **R. M. G. Brown** and others against the American Gas Coal Co., appealed from the Circuit Court of Monongalia County, that **federal income taxes constitute a prior lien.** Litigation in this case grew out of the fact that after the Knob Coal Co. had been sold by J. M. G. Brown, Robert D. Hennen and others to the American Gas Coal Co. for \$300,000, on which a cash payment of \$125,000 was made, when there was a default in payment action was brought, charging insolvency and when the case was referred to a master, unpaid income taxes were given a prior claim, such unpaid income taxes amounting to \$35,166.66 plus interest. Brown and his associates filed an exception to the finding of the master and the court sustained such exceptions and gave the trust lien priority, that portion of the decree of the lower court being reversed by the Court of Appeals. The Circuit Court held that federal income taxes did constitute a lien against the property but placed it after other liens on the ground that the federal government had failed to assert and establish its lien for unpaid income taxes.

C. E. Reese, gas and electrical engineer, has been appointed general manager of the Bluefield Gas & Power Co., Bluefield. This is a Sanderson & Porter property. Mr. Reese has been connected with the Westinghouse Electric & Mfg. Co., as section head stoker sales and publicity department, Philadelphia, Pa. He has been actively engaged in the Stoker Manufacturers Association as secretary of the publicity committee and chairman of the advertising sub-committee. He was formerly combustion engineer with Henry L. Doherty & Co., New York City, and assistant engineer with the Illinois Public Utilities Commission, working in Springfield and Chicago.

The U. S. Circuit court of Appeals at Cincinnati has affirmed the verdict of a lower court at Cleveland in awarding judgment of \$440,000 in favor of the Main Island Creek Coal Co. against the Cleveland & Western Coal Co., of Cleveland. There was an arrangement, it is alleged, between the two companies under the terms of which the Cleveland & Western company was required to deliver as much coal at tidewater for the Main Island company as that company delivered at the lakes for the Cleveland concern. The Main Island company in its suit alleged that at the end of the lake season it had shipped about 60,000 tons more than had been delivered for its account.

J. A. Blake has resigned as mining superintendent at the Glen White plant of the E. E. White Coal Co., and has been succeeded by **E. E. Jones**, who has been the superintendent at the Statesbury plant for some time. Mr. Blake was presented with a gold watch by the company at a farewell function. He also was presented with a gold chain and B. P. O. E. emblem on behalf of the Glen White Mining Institute and the official force of the E. E. White Coal Co.

Owing to a falling off of orders, the operators in the Mountain Park coal field, Saskatchewan, are **laying off about 500 men.**

The New England Fuel & Transportation Co. of Grant Town, W. Va., has contracted with the Roberts & Schaefer Co., for the installation of a screen and loading booms in its No. 3 tippie, at Lowsville.

Carl Scholz, vice-president and general manager of the Raleigh-Wyoming Coal Co., with mines at Edwight, in Raleigh County, and at Glen Rogers, in Wyoming County, has announced the appointment of **Walter Stevens as general mine superintendent at the Glen Rogers mine** of the company. The new general mine superintendent at Glen Rogers was associated with Mr. Scholz when the shaft at Valier, Ill., was sunk, that ranking as a record breaking performance, since work was commenced on September 1, 1917 and two shafts 612 feet deep had been sunk by April 1 and coal was being hoisted by the latter date. Mr. Stevens succeeds Edward Nicholson.

All the holdings of the **Macbeth Coal Co.** on Rum Creek in the Logan district of West Virginia, owned in large part by John Laing and associates of Charleston, has been purchased by the **Logan Eagle Collieries Co.**, headed by Walter R. Thurmond, former president of the Logan Operators Association and general manager of the Thurmond Coal Co. and of the Argyle Coal Co. The consideration involved is said to be in excess of \$1,000,000.

The judgment of the Circuit Court of Kanawha County in the case of the **Fayette-Kanawha Coal Co.** against the Lake & Export Coal Corporation of Huntington has been reversed by the West Virginia Supreme Court in the suit involving alleged breach of contract. The upper court set aside a verdict of \$50,281 for loss of anticipated profits, but the appeal court in its decision asserted that the possible production of one of the plaintiff's mines, not in operation, should not be considered.

WASHINGTON, D. C.

The Government Fuel Yards opened bids for anthracite and bituminous coal required between April 1 and June 30, 1924. There were 24 bids for supplying 24,600 gross tons of New River or Pocahontas mine run, the price varying from \$2.22 per gross ton, by the Lake & Export Coal Corporation of New York, to \$2.80, by William C. Atwater & Co. Thirty-four companies submitted figures on 10,000 tons of Maryland, Pennsylvania or northern West Virginia mine run, for shipment to the Capitol power plant, on the Pennsylvania R.R., the price range being from \$1.90, by the Valley Camp Coal Co., to \$3.30, by the Iron Trade Products Co.; for supplying 4,500 tons of the same coal for shipment to St. Elizabeth's Hospital, on the B. & O. R.R. 33 companies submitted tenders, the quotations ranging from \$1.80, by the Steamship Fuel Corporation, to \$3.14, by the Iron Trade Products Co. Six companies submitted bids on anthracite.

CANADA

Three recommendations were presented to Acting Finance Minister J. A. Robb and Charles Stewart, Minister of the Interior, by a delegation from the Central Council of Municipal Associations of Ottawa, that all retail merchants should put the analysis of the coal they sell on their invoices, that import duties should be removed from all machinery used in the manufacture of coke and its byproducts and from imported soft coal for conversion into coke; that the sales tax be removed from all byproducts, whether agricultural or chemical, of the manufacture of coke. Both ministers promised that the recommendations would be referred to government fuel experts.

An increase of over a million and a half tons of coal for the year ending September 30, 1923, is recorded in the annual report on the Nova Scotia mines. **The total output was 6,179,890 tons** as compared with 4,537,494 tons for the preceding year. There was an increase in local consumption of over 600,000 tons, while shipments to the St. Lawrence increased by nearly half a million. In his report Premier Armstrong stated that he hoped a scheme might be evolved whereby Nova Scotia coal might yet be coked somewhere on the St. Lawrence, its gas utilized and the coke go west to replace anthracite. He expressed the hope that the waters of the St. Lawrence might be sufficiently deepened so that Nova Scotian coal could reach Ontario and replace American bituminous coal and by semicoking replace the anthracite now imported from the United States.

Recently coal operators in the Edmonton field of central Alberta have been shipping coal by the **Canadian National Ry. to Port Mann**, and thence to Seattle. There seems to be reasonable hope that a good business will be developed by the mine operators with Puget Sound ports.

New Equipment

Oil Circuit Breakers with New Automatic Features

A line of indoor service electrically operated oil circuit breakers, in which are incorporated several new and distinctive features has been developed by the Westinghouse Electric & Manufacturing Co. These breakers are three-pole, single-throw, either non-automatic or automatic in operation, for capacities up to 2,000 amperes and alternating current voltages up to 25,000 with interrupting capacities rated at approximately 9,500 volts and 13,000 amperes respectively. They are particularly adapted to the control of alternating-current circuits of large capacity where the voltage does not exceed 25,000 volts. Each of the two forms has a different maximum interrupting capacity but the details of construction are similar.

The two outstanding features in the construction of this type of breaker are its compactness and its ease of installation. No intermediate structure walls are required for supporting the individual poles; all of them are supported from the common steel top. The breaker is supported by means of anchor-plates set in and projecting from the cell walls. The steel top of the breaker, which rests on these plates, is bolted securely in place. Where space is of prime importance, a saving of almost 6 in. per three-pole breaker can be made in length of cell structure by the use of steel compartments instead of concrete compartments. The space between the breaker top and the floor, in front of the tanks, is covered with removable doors, each consisting of a metal frame with asbestos panels and hinged at the top.

The oil tanks of the CO breakers are

Control Relay Makes Tripping Completely Automatic

The operation of the release coil of the control relay is designed to trip the breaker irrespective of the fact that the operator may be holding the control switch in the closed position.

seamless and die-pressed from heavy sheet steel. They are so fastened to the steel top that an oil-tight joint is secured. Each tank is equipped with a muffler, so that when the breaker opens a heavy short circuit, the air in the top chamber is forced out through the muffler in advance of the arc gases rising through the oil. This eliminates the possibility of a violent explosion in the breaker structure from the mixture of oxygen and arc gases. The rupturing capacity and the severity of the duty cycle which a given breaker structure will handle are thereby greatly increased. To prevent arcing between contacts and tanks, a set of removable flame-resisting insulating linings is used in each tank. The inner layers

of these linings are of asbestos; the outer layers, of micarta. Oil gages indicate the level in each tank.

The breaker is operated by a unit type solenoid mechanism mounted above the poles on the top of the steel bed plate forming the cell top. After the breaker is closed by the solenoid, it is held in the closed position by a hardened steel latch which in turn automatically engages with a trigger. The oil circuit breaker is equipped with a special control relay panel which is provided with a two-piece contact arm and release coil. As soon as the circuit breaker is closed by the operator in the usual manner, the pallet switch on the breaker energizes the release coil of the control relay. This release coil opens the contact of the control relay, irrespective of the fact that the operator may hold the control switch in the closed position. By the use of this special control relay, full automatic protection can be secured where the breaker is used in connection with overload relays and current transformers.

Electric Capstan Car Puller

The Silent Hoist Co., of Brooklyn, N. Y., has developed a car puller which they claim is powerful, compact, waterproof, dirt-proof and fool-proof. When used for placing cars, one end of a manila rope is hooked to the car and a few turns are made around the capstan head. When the free end of the rope is gently pulled the cars may be easily placed wherever desired.

The equipment consists of a Silent Hoist vertical capstan winch driven by an electric motor, or a gas engine. This equipment is all mounted on a self-contained fabricated steel I-beam base. The capstan is driven through a self-locking, non-reversible, worm gear drive consisting of a phosphor-bronze worm-wheel meshing with a nickel-steel hardened, ground, and polished worm. All thrust is taken by a ball bearing and the entire gear drive is inclosed in a gear case.

The entire machine is unusually compact, taking up a space of 22 in. by 44 in. The shipping weight of the unit complete with an alternating-current motor is about 750 lb., and with a direct-current motor the weight is approximately 950 lb.

The Model T-5 car puller has a rope pull of 5,000 lb. at 25 ft. per minute and will easily pull two average loaded railroad cars.

Oil Circuit Breaker

A 1,200-ampere, 25,000-volt, three-pole automatic circuit breaker with doors removed from two units and tank removed from one unit, showing heavy contact construction.

Hoist for Car Placing

This little hoist can be fitted either with an electric motor or gasoline engine and is especially suitable for spotting cars under the coal chutes.

Number 13

A Near Way to Oil and Coke

TWO problems of the domestic users of anthracite have been driving them to oil, to coke and even to bituminous coal—shortages of anthracite and its occasional poor quality. When a consumer buys coal, much of which came unwashed from some culm bank, he becomes utterly disgusted with anthracite.

Reputable operators declare he should sally forth and find out where he can get, say, Lehigh Valley, Glen Alden, Philadelphia & Reading or some other reputable coal unmixed with fuel of a lower quality. He should canvass all his friends to find out what company is delivering such coal. He should go far afield if necessary and buy his coal from some distant point even if he should have to pay a big price for delivery. Or he should band himself with other neighbors, buy a car-load from a reputable producing company, hunt up a teamster and open a set of books, making charges against, and collecting from, the recipients of the coal.

Perhaps he should, but then, perhaps his time is worth something. Then also he is not sure that he would be able to collect his money promptly and is not confident that he would get thanks instead of blame for his self-imposed activity. The coal may arrive too late or may not satisfy his friends or may be too expensive, being bought at the highest price at which "independent" coal is sold. Then again, the teamster may impose on him or fail to unload the coal promptly causing him to pay demurrage. The unloading will be expensive for he has no facilities for doing it. There are no scales, perhaps, convenient on which the coal can be weighed. So he decides not to make the attempt.

If he has to look around for a dealer who sells only good coal and is fortunate enough to have it on hand, that probably will take some time which he may not have to spare and when he does he may have to pay a high price for the hauling. As for buying on the statements of friends, that is not quite safe, for in time of shortage many kinds of coal good and bad are sold by the same dealer.

Consequently, he goes to oil or it may be to coke or even in some cases, where that is possible, to bituminous coal. If he puts in the first he has to expend so much for equipment that he is loathe to go back to anthracite. If he buys coke, he finds he has a little difficulty in adapting himself to it, but after a while he is apt to like it and he becomes a permanent coke buyer.

With bituminous coal he will have a little more trouble, perhaps an explosion or so, not severe, of course, but troublesome nevertheless, some annoyance from dust and soot and a few extra fires to light on some cold morning or on a return from a party or a theater. But perhaps he can excuse that because his cost is less and some of the difficulties can be avoided by careful firing, breaking up clinker, wetting down the coal pile and choosing the right kind of bituminous fuel. So he also may be lost to the anthracite market,

for a while at least, for how long depending largely on his location with regard to the anthracite region and on the forbearance of his neighbors.

No matter whether he did right or wrong, that is not the point at all. He did it, and the anthracite market is the loser and mark you! the owner of the unwashed culm bank does not suffer the loss. That individual is not continuously in business. It is the company that looks to stay in the market that loses that trade, not because it has been dishonest but because it has said it was none of its business if other people did fleece the purchaser, because it has said that the buyer should beware and if caught should demand restitution, because it has believed its own bright coal would "shine like a good deed in a naughty world," whereas it did nothing of the sort. Good coal, after a few deliveries of low-quality product, shines only like a "will o' the wisp."

Those Bad Boys of Nova Scotia

PRESIDENT LEWIS' good right palm must itch to spank the reds of the Nova Scotia union district. For years, in that distant corner of unionism, they have been cutting up naughtily. When Lewis spoke they thumbed their noses and threw mud balls at the union king like bad boys on the other side of a creek from their scolding parent. And now they have upset all precedent by refusing to accept a wage advance the organization got for them. Dear, dear, dear! What to do! What to do!

The difficulty dates back almost to the very year in which the independent Nova Scotians in their separate union were induced to join the United Mine Workers. Their independence within the union has grown steadily stiffer. About 1921 it became painful. Bolshevism colored the district so vividly that the miners once voted to join the Red Trade Union Internationale of Moscow, and later withdrew their petition. Toward Lewis, since then, the policy of the district evidently has been: "No matter what he wants; we don't want it."

In November, 1921, when their agreement expired, Lewis urged them to demand a new one; so they did not. Two months later, operators cut wages thirty-seven per cent. Lewis said strike; so they worked. He advised them later not to "strike on the job"; so they did that, too. When the great strike of 1922 started, Lewis wanted them to come out and make it unanimous. They stayed in and dug union coal. In August, when they finally struck, Lewis thought they should demand a return to 1921 wages. They accepted reinstatement of only seventeen per cent of the thirty-seven per cent cut. This left them twenty per cent short of 1921, and they went back to work under contract at \$3.25 a day—the lowest day rate in any union field.

Then, last fall, while Lewis was negotiating with the anthracite operators and publicly declaring the union's belief in the sanctity of contracts, the union miners of

Nova Scotia violated their contract by striking. *That* mudball spattered Lewis good. The MacLachlans and Livingstones of Nova Scotia were viciously happy. "What do you mean by doing such a thing?" Lewis wired. "None of your business" they replied. Mr. Lewis' collar nearly burst. He dissolved their district organization and named provisional officers. These are the ones who induced the operators, Feb. 11 of this year, to raise day men twenty-five and thirty cents, loaders seven cents a ton and pick miners eight cents. And now the district rejects the increase 5,617 to 3,145!

This sort of thing, together with recent periods of violence, makes Nova Scotia a problem for Lewis, the coal operators and the whole industrial fabric of eastern Canada. About the only hope lies in a change of attitude by the men. To bring this about the operators can only pay fair wages, adopt a policy that is stern but absolutely just, peaceful and humane, and stick to it. Lewis, to regain district control and respect for the contracts he makes, might try colonizing Nova Scotia with some of this excess of loyal union men from the United States—if any willing loyalists can be found.

Meantime if the 5,617 anti-Lewis miners were to go on working at the new wage but spitefully scorning the contract, the region would be non-union, and the bad boys of Nova Scotia would have accurately landed another mud ball. Oh for a chance to wield that good right palm!

At Castlegate

UNFORTUNATELY the mines in the Rockies have their own particular troubles or rather they have the troubles of other mines in accentuated form. We may therefore look to them to set the pace for the rest of us. Many excellent practices originated around Castlegate. Many schemes for making mines safe came from those workings, and good plans they were too, though this disaster shows they were not good enough.

The Utah Fuel Co. will have to start over again and earn a reputation by being among the first to protect its mines by adobe or rock dusting. The material is readily available, only too available, most people will say who have traveled through the arid stretches nearby Castlegate with little but adobe in sight over large areas.

Dr. Wheeler said the other night that no one should be afraid of firedamp. It simply won't explode unless the percentage of methane reaches the explosive limit. And so it is with coal dust, it won't explode if every last pile of it is so wet that it will ball in the hand and if the right explosive is always rightly used and if trolley wires don't fall and arc, and if a half a dozen kinds of mistakes aren't made.

Coal dust is perfectly safe, if all precautions are always taken everywhere, but they are not, never were and never will be, so why expect it in any one instance. Resting lives and property on eternal and universal watchfulness when men are known to fail frequently is a senseless gamble with death if better ways are known. Discipline is all very well as far as it goes, but any safety which has to rely heavily on discipline will sometimes fail and if a mine can be made so safe that discipline is rendered less necessary it will avoid startling headlines and be less likely to subject its owners to a staggering loss.

Rock dust is not only a cure for explosions but an active antidote. It will not only prevent them but limit

them if they start. A little breach of discipline that will let them commence will be corrected therefore by the condition of the roadways that such explosions will meet as they travel on their way. Consequently it is a double protection, one half of which, that on the main roadway being subject to ready and easy inspection by everybody. The color of the dust is a reliable guide, and the frequency of the application is a ready matter of record.

It is not an inexpensive cure. However, in Utah it is not so expensive as in some other states which do not have adobe to dust with. And after all a million dollars or more of a loss such as the Castlegate mine sustained is so large that any mere maintenance cost would be years in equalling it. With that in view, rock dusting becomes a saving rather than an expenditure and wise indeed is he who does not omit it.

Small Mines Have Advantages

TO HEAR the statisticians talk, one would think the small mine had never a chance, but with its short haul, its low ventilating pressures and the possibilities of greater co-ordination between its individuals, conditions are not really so perplexing after all, if care has been taken to keep the mine in good operating condition. The small mine does not as a rule have much capital expenditure on which to pay interest. It is usually so located that its drainage problems are not difficult. Given good management the small mine should be able to hold its own, till it gets too much extended, till it becomes that saddest of all mine properties, a big mine with a small capital outlay.

It used to be and probably still is true that many mines continue operating till they reach a certain extension when they become snuffed out from lack of money to provide for the needs of so far-flung an operation. Happy is the man whose mine is nowhere over a mile from the tippie. Some people may be willing to buy a mine on the basis of trackage length but after they have operated it awhile they realize that if they want cheap coal long haulages are not desirable.

Airtight Compartments in the Coal Industry

AS ONE travels around the coal regions he realizes how provincial parts of it are. Perhaps least provincial sections are Pittsburgh and Chicago. Possibly St. Louis might be added. There are sections bound in by mountains with poor means of communication which positively do not have any connection with the outside except through technical literature. The towns in which these secluded people live may be large enough to fill the outsider with interest and respect but the roads leading from them run in only two general directions or they are so far away from other mining sections that technical provincialism is quite marked.

The only cure is in technical reading. First-hand information is not available. The press of business prevents traveling, and neighboring operators do not invite visitors, so nothing remains but the written word. Where social life is well developed, where Rotarians, Lions, Kiwanis, Masons, Elks, Moose and other organizations monopolize the spare moments there is no time for study and the isolation is complete. Still, progress is the word of the hour and more time certainly should be given to obtaining from books and periodicals what fails to travel by word of mouth.

Steeply Pitching Coal Beds, Undercut by Machine, Are Tapped by Slope in Shales Below Them

Seam Gradient 58 per Cent—Coal Does Not Crop Anywhere on Face of Hill Fronting Tipple—Slope Will Not Cut Seam Till It Has Been Driven 2,600 Ft. but a Slant Is Provided to Tap Coal 1,900 Ft. from Portal

BY CHARLES M. SCHLOSS
Denver, Colo.

BACK in the frontier days of the West, "Remember the Alamo!" was the stirring battle cry of the patriot Texans, when, fighting against heavy odds, they annihilated the Mexican forces led by Santa Anna and made Texas an independent nation. Today a new Alamo is being made memorable. In spite of obstacles, and in the face of adverse conditions prevailing in the coal industry, a mining enterprise headed by W. B. Lewis of New York is bringing one of the newest mines of Colorado, the Alamo, into production. The name chosen is reminiscent of one of the most picturesque episodes in the romantic past of the great West.

Careful search was first made for a virgin territory containing a coal equal in quality to that produced by the Oakdale mine—also situated in Colorado and operated by the interests that control the Alamo. Finally a tract of 640 acres lying 16 miles north, and slightly to the west, of Walsenburg was optioned and drilled, with the result that two workable beds of coal 39 ft. apart were proved suitable for mining. The upper bed is 6½ ft. thick, and the lower contains 10 ft. 5 in. of hard bituminous coal believed to be the Cameron seam. The drill holes proved about 18,000,000 tons in the two measures.

In order to develop the mine quickly and place coal on the market in the least possible time, an executive committee consisting of Harry F. Nash, vice-president and general sales agent, E. H. McCleary, general manager of operations, and J. H. P. Fisk, engineer, all of whom reside in Colorado, was appointed. These men had authority to adopt plans, purchase material, and in fact, push through to successful conclusion all construction and development. All this work was done by con-

tract under the supervision of Mr. McCleary and the engineers, Douglas, Corey & Fisk, of Trinidad, Colo.

With the necessary preliminaries attended to, active work was started on Jan. 1, 1923. Since that time a camp has been constructed, mine buildings erected, and five miles of railroad built as a connection between the mine and the joint track of the Colorado & Southern and the Denver & Rio Grande Western which serves the mines between Walsenburg and Tioga, the former terminus of the line.

The water problem at this mine was solved by sinking a well, 11 ft. in diameter, through 45 ft. of quicksand. In this operation a continuous concrete ring with a metal cutting shoe was employed. A flow of 200 gal. per min. was obtained. The well is located a few feet from the power house, and the water is pumped through a 4-in. wrought-iron pipe line, a mile long to an elevated reinforced-concrete tank of 50,000-gal capacity. Ample pressure is thus afforded for fire protection at both tipple and townsite.

The Alamo camp is situated on a hill with the Spanish Peaks towering in the distance on one side and the supposedly volcanically formed Black Hills on the other, in the immediate vicinity. It thus possesses real picturesqueness. The mine is separated from the town by a dense piñon grove, rendering it impossible to see the mine from any part of the town. This physical detachment lends an atmosphere of independence to the camp; the workman at home at the end of the day is not constantly viewing the scene of his labors.

Twenty homes, now completed, are built in two lines paralleling a central plaza or boulevard, constituting one arm of a cross. They represent one-quarter of

FIG. 1
Alamo Mine

This shows the general location of mine and camp. It will be observed that the power house and spray pond are on a point where two arroyos converge. Coal is brought to this plant from the tipple by means of a conveyor line. Although the mine workings underlie the town the mine buildings cannot be seen from it, being obscured by a pinon grove.

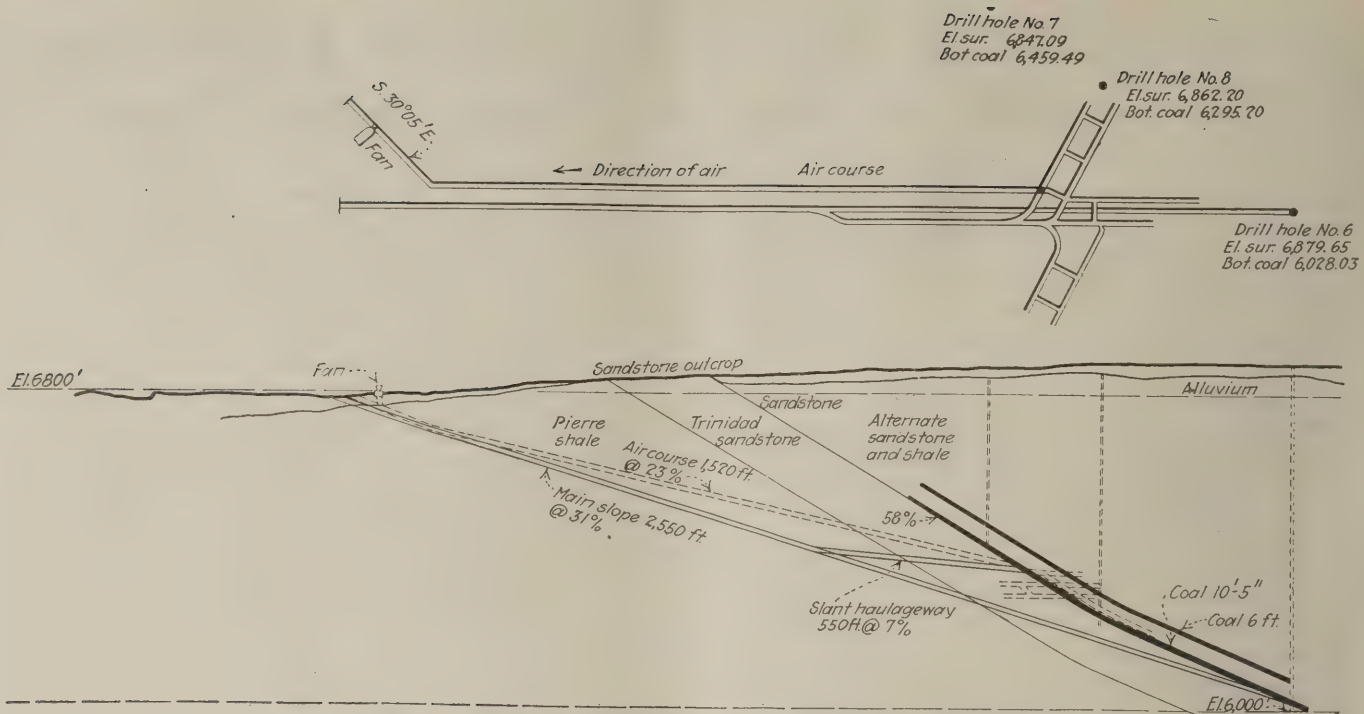

Fig. 2—Plan and Elevation of the Rock Slope, Slant and Coal Workings

The coal pitches under the hill at a 58-per cent gradient, the main slope being driven in the rock underneath it at a grade of 31 per cent. The airway on the other hand is driven at a 23-per cent gradient. A 7-per cent slant haulageway is driven off the main slope 1,300 ft. from the portal, reaching the coal at the same elevation as the airway

the contemplated townsite. All special town structures, residences and other buildings will occupy positions in one or other of the four quadrants. In outside appearance the houses follow the architecture of the world-famous Alamo, as in fact do all the other buildings. Several bungalows of different designs have been erected, all containing four rooms and two closets and all made of cement brick, manufactured by the company at Alamo. This has proven a means of materially reducing the cost of both construction and maintenance.

Because of the position of the coal the underground development is of a most unusual character. The two beds underlie a hill and dip steeply from west to east. The pitch, beginning at the western edge of the deposit, is 58 per cent. This decreases materially, however, as the measures are followed to the eastward under the hill. On the western slope of the hill the coal does not outcrop, but the sandstone which is directly below the coal outcrops several hundred feet above the valley floor where the tippie is located.

From the foot of the hill, the main slope and air course have been driven straight eastward. The inclination of the slope was fixed at 31 per cent so as to tap the under side of the lower seam 2,600 ft. from the portal. The slope is 8x10 ft. in over-all cross section, giving 7x9 ft. in the clear.

The plan called for entrance into the coal at two points. Thus, when the main slope had been driven 1,300 ft. through the Pierre shales, a slant was turned off on a 7-per cent down gradient. This penetrated the stratum of Trinidad sandstone lying above the shales and immediately underlying the coal and tapped the lower coal bed at a point 1,900 ft. from the portal. Thus coal can be produced while the rest of the main slope is being driven. The development of the upper or western, part of the mine is being projected from this slant. These workings are expected to supply the mine's tonnage for the next four or five years.

An aircourse was sunk at the same time as the main slope and on a 23-per cent gradient. This intercepts the coal at the same elevation as the slant. Both passages have been timbered throughout their entire length in the shales with three-piece red-spruce timber sets placed on 5-ft. centers and lagged on top and on both sides.

The main slope is as straight as an arrow, adhering uncompromisingly to the set pitch and direction. Manager McCleary says of it: "There were several days when at a certain hour the inclination of the sun's rays coincided with the inclination of the slope, and the actual sunlight lighted up the face, 1,500 ft. in. The alignment and uniformity of grade will be so exact that this condition will prevail at a point 2,600 ft. from the portal where the coal will be struck."

The pitch of the bed, 58 per cent at the west side of the property, might prove alarming to one unaccustomed to the methods to be employed at Alamo. Many old-timers, when considering the steepness of the pitch, would doubtless say: "That's easy; drive level entries and turn chutes up the pitch." They would fail to take into consideration that the market to be served demands lump coal. Lump commands a high price, but with chute mining, because cutting machines could not be used up the pitch, the coal would necessarily be shot off the solid, and this method of mining yields a relatively small percentage of lump. Consequently, if the coal were mined by chute methods, the income from the property would be small.

It was realized that a better system was available, a system that would yield much greater financial returns. This was the panel system with level cross entries driven at right angles to the slope, butt or panel entries down the pitch and rooms turned on the strike. Cutting machines thus can be applied successfully, and the percentage of lump substantially increased.

It is interesting to know that shortwall machines are successfully operating on this pitch of 58 per cent.

The work done thus far has been the driving of the cross entries on the level and the dip entries on the pitch. The machine sumps in at the lower rib and cuts to the top without appreciable effort. Because of the width of the cars and the 42-in. gage used, the track, though laid near the lower rib, is considerably higher than the lower corner where the machine loads and unloads from its truck. It is no easy task to load it from this depression.

Two machines, a Goodman universal control and a Sullivan Ironclad were purchased. These undercutters operated on 3-phase, 60-cycle, 440-volt current. Both have their reels mounted on extensions from the truck. This is necessary, because the machines are handled by hoisting ropes and the trailing trucks, if used for carrying the reels, would frequently derail when negotiating curves.

Experience in other mines has shown that this is what happens, though it is admitted that trailing trucks are advantageous in flat beds. Operators of the Sullivan equipment use jack pipes to maneuver the machine at the face, whereas Goodman machine runners drill holes in the ribs, set anchors in them to which they hook their ropes, thus avoiding the labor of handling the heavy jackpipes necessary for this high coal.

Hoists placed at the head of each panel slope will gather the loads from the room necks and deliver them to the partings on the level cross entries. Thence, locomotives will pull them to within reach of the main hoisting rope. The panel hoists will be so placed that no rope from them will cross a haulage road. The main hoist, located in the power plant, is rated at 25,000 lb. of rope pull and a speed of 900 ft. per minute. The diameter of the drum is 84 in. and the drum has a 60-in. face—large enough to wind 3,500 ft. of 1½-in. rope in not to exceed four layers. It is equipped with a 96x12-in. wood-lined face, parallel-motion, and oil-operated post brake. This machine is driven by a 600-hp. motor.

The slope track is laid with 60-lb. steel, the level entries with 30-lb. and the rooms and panel entries with 20-lb. rails. The cars weigh 2,800 lb. and hold an average of 5,000 lb. of coal. Being equipped with roller bearings, they are easily moved.

Each pair of level entries will be about 2,600 ft. long and will be served by a separate split of air which will also ventilate the three to four sets of panel entries turned off them. Six pairs of levels will be turned off each side of the main slope. This means that a like number of main splits of air must be provided. A cement-block undercast has been built under the first

Fig. 3—Section and Elevation of a Room

This shows the difficulties under which the undercutting machines must be operated. Despite these handicaps, which will be at once appreciated by mining men, the undercutters have given excellent satisfaction.

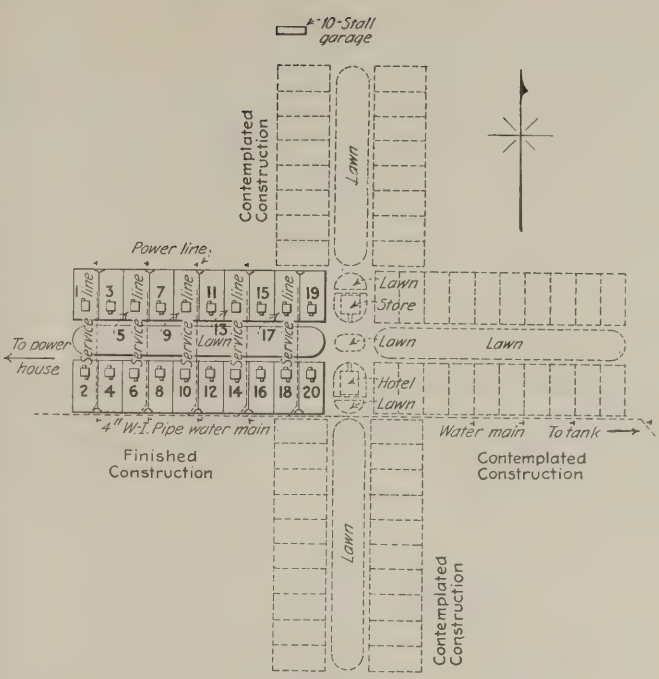

Fig. 4—Alamo Village Laid Out with Grass Plots on Street Centers

Only one arm of the cross has as yet been completed but the entire projected layout is shown in this illustration. It will be noted that a simple, neat and aesthetic design has been attained.

left or north level. This is provided with a concrete roof reinforced with 20-lb. rails and old haulage cable. Because of the heavy pitch of the coal an overcast would have made an impossible traveling way for men and mules. Air is exhausted by a 5x7-ft. multi-blade fan with a capacity of 150,000 cu.ft. per minute against a 2-in. water gage. This ventilator is reversible.

The tipple, built largely according to Mr. Nash's suggestions, was designed so as to provide well-prepared coal. The main hoisting rope pulling over the tipple deck, lands the trip on a car retarder, from which the cars are fed one by one over the scale to the rotary dump, thence into the kickback, and onto the empty track. Coal is fed from the dump hopper to the screen. The small sizes are re-treated in a revolving screen fed by a continuous bucket elevator, and from it deposited in two bins.

Nut and lump pass to loading booms which are hinged and pivoted at the screen ends so that they may move in both horizontal and vertical planes. The discharge ends are carried by 3-ton overhead electric hoists, suspended by trolleys from I-beams spanning the respective tracks. When swung at an angle across the track the goose-necks in the booms permit them to reach over the sides of gondolas and discharge near their bottoms.

If swung parallel to the tracks, the booms discharge to curved right-angle chutes leading to extension box-car loaders, a belt type for nut and a drag type for lump. These loaders reach over 16 ft. into the ends of the box-cars and load with a minimum of breakage. Cars can be filled to capacity at a conveyor speed of 290 ft. per min.

A cement-brick building of Alamo architecture, 60x70 ft. in plan, houses the modern power plant, designed by Wood & Weber, consulting engineers of Denver. The two dominant influences in the design of this structure were the desire for economy in equipment and for a minimum of operating labor cost.

By a rope-and-button conveyor slack coal is transported

from the bin at the tippie across the arroyo to this plant, a distance of about 400 ft. Additional storage of coal is provided by a pit into which this conveyor discharges. When a chain-operated rack-and-pinion gate near the discharge end of this conveyor is opened, the coal drops into a screw conveyor extending across the power plant to small hoppers over the stoker magazines. A centrifugal discharge elevator is provided, to raise the coal in the pit to the same screw conveyor. This feature insures operation of the power plant in case of a breakdown to the rope-and-button conveyor or of a shortage of slack in the bin at the tippie.

The boiler equipment consists of two 250-hp. marine-type water-tube units originally built for the Emergency Fleet Corporation. Both are stoker-fired. Water is automatically maintained at the proper level in the boilers by a feed-water regulator, and the forced draft is automatically controlled. A drag-chain conveyor disposes of the ashes at the rear of the plant.

An electric hoist was considered more economical than a steam-actuated machine under the conditions prevailing at Alamo. Heavy fluctuations in demand on the 600-hp. hoist motor necessitated the installation of a 1,250-kw., 2,300-volt, 3-phase, 60-cycle turbo-generator, rated at 80-per cent power factor. Steam is exhausted

into a jet condenser to which cooling water is supplied from a concreted spray pond. All the water entering this pond is first passed through a softener. Once the pond has been filled with softened water it is necessary to treat only such makeup water as is needed each day.

The complete power plant including not only the boilers but the hoist also is housed in the one large room. To keep the investment down, only the bare necessities of operation have been installed. The economy practised can be appreciated from the fact that the installation cost per kilowatt of capacity including the hoist, was less than \$100. The arrangement is such that additional generating equipment can be added from time to time as needed. For the present, an engine-driven alternator used in the temporary plant employed for construction work, is being moved to the power plant as an emergency unit.

Taken all in all this property is expected to become one of the most interesting in Colorado. Though only the lower bed is to be worked for the present, the upper one contains 6 ft. of good coal and will be entered whenever the time seems opportune. It is possible therefore, that the coal industry of the West, may have occasion to "Remember the Alamo" for a long time to come.

Fig. 5—Everything at Alamo Except the Tippie Is Built of Permanent Materials

At the top, the office and slope mouth; in the center, the tippie, and at the bottom, two bungalows. Concrete, reinforced concrete and cement brick are the materials used. This kind of brick can be manufactured at the mine more cheaply than ordinary brick

can be purchased. Appreciable savings were accordingly effected in house and general construction. Every building in Alamo is of characteristic Mission architecture, simple but effective, the camp as a whole presenting a harmonious picture.

Ormonde Colliery, Butterley Co. near Derby

How Washer at British Colliery Readily Treats Mixed Coals of Widely Varying Character

Coal Up to 3-In. Cube Is Separated Into Four Sizes and Each Size Separately Washed — Adjustment to Suit Any Kind of Coal Readily Can Be Made

BY C. H. S. TUPHOLME
London, England

ARHEO-WASHER designed to prepare 100 tons per hour of coal up to 3-in. cube—the first washer of its kind to be erected in the British Isles—is located at the Butterley Co.'s Ormonde Colliery, near Derby. The unwashed coal from the screening plant is brought by a canvas conveyor, *A* (see Fig. 1), running at 350 ft. per minute and capable of conveying 100 tons per hour. The coal is delivered into the coal storage hopper *B*. Provision also is made to enable coal from other shafts to be washed by installing dumps, *C*, for end-gate cars. These are so arranged that it is immaterial which end of the car is foremost. These dumps each have a separate motor, spur drives to a rope drum which is connected to a block and tackle arrangement which lifts the hinged platform and so tips the car. This method provides a rapid means of emptying cars without the need of clips or damage to the sides of the car.

From the bin for the unwashed product the coal is raised to the shaking screen, *D*, by means of the elevator *E*, which has a capacity of 100 tons per hour. The frame is dustproof and has an adjustable sliding door at the bottom to regulate the feed. The opening and closing of this door sets up enough disturbance in the

bin to prevent the coal from arching and so destroying the regularity with which the coal is delivered to the elevator. The unwashed coal then passes down a forked chute, *F*, having a regulating door to insure equal distribution of the coal to each of the side-by-side balanced shaking screens, *D*, which size the coal into 0 to $\frac{3}{8}$ in., $\frac{3}{8}$ in. to 1 in., 1 in. to $1\frac{1}{8}$ in., $1\frac{1}{8}$ in. to 3 in. With this type of screen the coal has a transverse zig-zag movement down the perforated plate, giving effective screening. Although these screens are working at a considerable elevation above the ground they are so well balanced that it is impossible to detect any vibration of the building.

The various sizes of coal are then delivered from the screens by chutes to the top of their respective bins, each having a capacity of 50 tons. These bins are provided with spiral chutes *G* to prevent any likelihood of breakage.

Following the 0 to $\frac{3}{8}$ -in. coal through the process of washing, the door at the bottom of the bin is opened, allowing the coal to join the flowing water in the top trough. It will be readily understood that in the trough a classification takes place between the shale and the coal, its greater specific gravity and its frictional

resistance to travel, causing the shale to form a bed in the bottom of the trough. It would now be possible to allow the shale to fall through a slot in the trough, but in so doing the suction would cause some coal also to fall with it. To prevent this, an ascending current of water sufficiently strong to eliminate this possibility is introduced in the slot. Considering the installation for 0 to $\frac{1}{8}$ -in. coal as a whole, it will be noted that there are three washing troughs, having in all twenty-four traps.

The velocity of the ascending current at the first two traps on the top trough is such that most of the shale is eliminated, the last trap on the top trough being set to pass a mixture of coal and shale. It will be readily understood that a layer of shale consisting of smaller and smaller particles, extends almost the full length of the top trough, so that all that is required is that the intermediate traps between the first trap and the last on the top trough shall be regulated to suit the condition at their respective sections of the trough. In the second trough the traps are similarly adjusted, but as the quantity of coal has considerably diminished, the shale can be more readily extracted, while in the third trough we have a mixture still containing coal. This mixture is conducted to the rewash elevator *H*,

and raised to the head of the first trough to be re-washed.

The pure shale is collected in a further trough and carried by it to the final shale elevator, *K*, to be dumped into the shale hopper, *L*. By this arrangement some coal is allowed to pass with the shale so as to make sure that all the shale is extracted. This coal is recovered by rewashing. The clean coal passing over the ends of the top and second troughs is conducted to the foot of a slow-running elevator, *M*, having perforated buckets and a capacity of 50 tons per hour, whence it is delivered on to the distributing scraper conveyor, *N*.

To reduce the moisture in the fine clean coal, a new feature has been incorporated in this scraper conveyor. As the coal is scraped along the top plate the resistance to motion causes the coal to be compressed. This squeezes out the water, which passes through a series of perforations. Any coal that may also pass through is recovered, and by means of a chute is delivered to the trough. Then, by means of doors on the lower tray, the coal is distributed to some one of the five storage drainage bins, where it is allowed to drain for a few hours. As is generally understood, it is the particles of clay which tend to hinder drainage from the bin, but by this system this undesirable material is removed in the washing.

To convey some idea of the flexibility of the device, and how readily the installation may be adjusted, this plant has on several occasions washed batches of 60 tons of coal from other mines where the coal has quite different characteristics from that usually washed, and in a few minutes all the necessary adjustments have been made and results have been obtained as satisfactory as when washing the coal of the Ormonde Colliery.

In the treatment of the larger sizes of coal the door at the bottom of the bunker is opened, allowing the coal to join the flowing water in the trough. The classification is obtained in exactly the same way as for the fines, but instead of having three troughs only one is used. The reason for this is that naturally the larger classes of material need a shorter length to take up their relative positions in the bottom of the washing trough, and only two traps are required.

The first trap, *F*, extracts pure shale; the second, *R*, extracts any remaining shale and some coal. This mixed product is then raised by means of the rewash elevator, *S*, to the head of the trough to be re-washed. The shale from the first trap is raised by means of an elevator, *T*, where it is finally discharged into the shale

Fig. 1—Plan of Ormonde Washer Showing Treatment by Flow Method, Screens and Bins

Coal enters over a belt at *A* or by way of car dumps *C*, into raw coal hopper *B*. It is carried by an elevator *E* to a chute which feeds two screens *D*. These separate the coal into four sizes. Spiral chutes deliver the coal to four bins, one for each size. The finest size goes to the flow washer on the left. The fine coal is taken off the end, and the shale and rewash coal go to their respective bins. The elevator *H* carries the rewash back to the top of the head trough for rewashing. An elevator *K* raises the shale to the bin *L*. The clean fine coal is raised and drained by elevator *M* and conveyed by scraper conveyor *N* to two

bins over Road No. 4. In the two central flow-washers pure shale is removed at *PP* and rewash material at *RR*. The first is removed by elevator *T* and goes to the shale bin *L*, the second is returned to the top of the upper flow washers by elevators *SS* and re-washed. The fine coal goes to Road No. 2 or Road No. 3, according to the size, being elevated for the purpose in drainage mesh elevators *W*. The larger size is taken to screens *X* for sizing, the degradation coal going thence to the fine rewash tank for treatment on the flow washer for fine coal, the coal being lifted by elevator *H*.

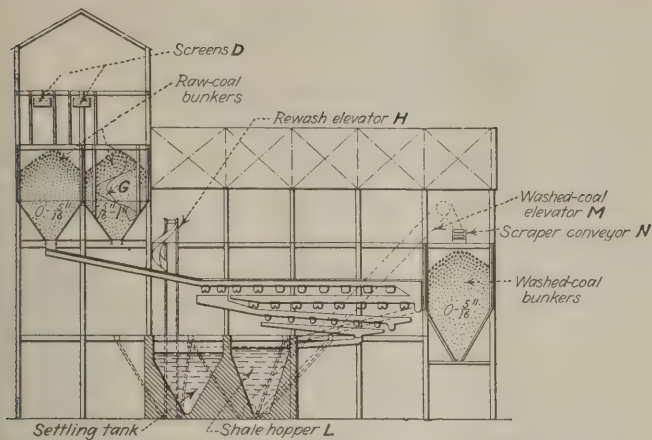

Fig. 2—Elevational Section Through Fine-Coal Washers
This elevation shows the three washing troughs with their twenty-four traps, with the screens D, the raw coal bunkers for 0 to $\frac{1}{8}$ in. and $\frac{1}{8}$ to 1 in. coal respectively, the rewash elevator H, the settling tank, shale hopper L, washed-coal elevator M and washed-coal bin.

bunker. The clean coal passing over the end of the trough is conveyed by means of a drainage mesh conveyor, W, to the small screen, X, where any fine coal is extracted and directed to the foot of the fine rewash coal elevator, H.

The washed coal passing over the screen is loaded directly into railroad cars by means of a telescopic loading chute, Y, as shown in Fig. 1. The Ormonde washery has two washers for the preparation of large sizes which are, with the exception of the screen, quite similar.

From each of the tanks containing shale, fine washed coal and fine-coal rewash, the water overflows to a main settling tank, from which the main circulating pump, having a capacity of 90,000 gallons per hour, takes the clarified water and lifts it to the overhead tank, which provides the constant head of water for both the horizontal flow and the ascending currents.

In this system of washing little or no fine material is

caused by the actual process of washing, but the very fine particles already in the coal, which settle at the bottom of these tanks and of the settling tank, are, by means of flushing valves, collected in a sump. This material, which for the want of a better name is called sludge, is finally pumped and mixed in the tank with the fine washed coal.

By this method of dealing with the sludge the settling tanks do not need to be shoveled out and waste of material is eliminated. The percentage of sludge is small compared with the whole quantity of coal handled. The washed coal is very clean, the total ash content being well within the permissible limit.

The building is of steel, with $4\frac{1}{2}$ -in. brick paneling. The fine washed-coal bins and the unwashed screened-coal bins are of steel, brick filled in cement mortar, and lined with a thin layer of cement. The shale tank and the settling tank are constructed of brick-work in cement mortar and lined with cement. The fine washed coal and the fine coal rewash tanks were made of different materials in order to ascertain which of the two types was preferable as regards efficiency and relative cost. The washing troughs and curved chutes from the rewash elevators are constructed in reinforced concrete. This material is recommended for troughing when the water is of a corrosive nature.

Fig. 4—Screens

Above an elevation, below a plan. The screens swing side-ways and not end-wise which is the usual practice. Vibration is fully counterbalanced.

**FIG. 3
Troughs for
Fine Coal**

The fines are washed along the troughs at varying speeds depending on the specific gravity and shape of the material. Heavy and flat particles being slow fall readily into traps set in their path. A current of ascending water sustains the clean product. Middlings and coal are taken off at some of the traps and passed to the head of the washer to afford a larger quantity of material of a specific gravity greater than coal and less than slate, thus separating the two effectively and aiding in their segregation.

Fig. 5—Draining and Distributing Conveyor

To reduce the moisture in the fine coal a scraper conveyor is used which squeezes the coal through a series of perforations. Any coal which may pass through these holes falls on a chute and returns to the trough, an unperforated chute being provided for that purpose.

The roofs are supported by steel trusses and are covered with slate wired to running single purlins. The floors and gangways are of concrete. Alongside the installation, gantries are provided for inspecting the washing troughs, and for regulating the valves. The elevators, screens and conveyor are sturdily designed, with consideration given to facilities for lubrication, inspection and renewals. Each machine is provided with fast and loose pulleys, and the belts can be shifted from the inspection platforms. Generous walking room and staircases are provided everywhere.

The whole of the plant is electrically driven and is provided with five electric motors having a total capacity of 150 hp., only 100 hp. being needed for normal working of the plant. This is equivalent to 1 hp. per ton of coal washed per hour. The water required to compensate for losses in the coal is 40 gallons per minute. The labor required to attend to the actual washery consists of one man and one boy, two men being needed for the loading of the washed products.

Two different seams of coal are normally washed in this plant, the mixture of which is extremely variable. Sometimes (owing to temporary stoppage of one or the other of the shafts) the washery has to treat either one separately. The characteristics of washability of the two coals, however, are entirely different, the Kilburn coal, for example, containing twice as much dirt as the Low Main, and the pure coal of the former seam having a greater specific gravity than that of the latter.

In spite of the difficulties enumerated, the percentage of free coal contained in the shale varies between 0.9 and 1.7 per cent only and the total ash in the washed product has generally not exceeded 2 per cent above the fixed ash of the coal, although the sludge has been continuously mixed with the fine washed product.

One of the most striking properties of the plant is its capacity for reducing the percentage of pyritic sulphur. The total sulphur in the raw material is approximately 1.6 per cent, whereas in the washed product it is reduced to 1.11 per cent.

Fig. 6—How the Coarse Coal Is Washed

Only two traps are provided and neither have any ascending water. They take off rewash and slate respectively. The rewash goes back to the head of the trough and is put through the process a second time. The screen sends any undersize that may be formed back to the fine-coal washer. Some also goes through the mesh conveyor and joins the coal from the screen.

The Miner's Torch

Overrating the Value of Education

During the last few months of 1923 most all of the weekly and monthly literary magazines and especially the ones appealing to women, had articles marshalling support to Senator McCormack's proposed amendment to the Constitution designed to give Congress power to regulate Child Labor in the United States.

In most States children are already prohibited from working in mines until they pass the age of sixteen so the amendment in question would have little effect on the employment of children in mines, consequently mining men have paid little attention to the pending bill, but the magazines mentioned reach a large number of homes in mining communities and the possible effect of the magazine articles is worth considering.

Every article on the subject of Child Labor that I have seen starts off something after this manner: "It is no longer possible to suggest argument against the prohibiting of child labor; every objection that can be advanced has long since been proven absurd. Only two plausible reasons for allowing children to toil have ever been suggested. First: Labor is good for children. Second: Some communities need the earnings of the children. The rebuttal to the first is found in the records of our juvenile courts and to the second in banking statistics."

I am in no position to question the records of the juvenile courts and when it comes to banking statistics I am still more helpless, so of my own knowledge I cannot question the arguments put up by the opponents of child labor but of my own knowledge I can say that many of the parents who have been led to believe that education is a broad highway to success for all children may find that they have been misled.

The most pathetic figure that you can find around a mining camp is a hard-working foreman who has come up from the ranks and made a success, in spite of early handicaps due to poverty and lack of education, trying to place a son who has just finished college but who has never been allowed to labor with his hands because he was destined by his father to become an educated man that he might be spared the struggle of his father.

If we can accept the testimony of the men who have made the most conspicuous success of recent years even in the so-called learned professions, at least 75 per cent of the work which they perform consists of wearisome routine and in their capacity for hard work in spite of all of the drudgery we find the secret for all of their accomplishments. What chance then have the sons of self-made men to gain recognition in any profession when they have been led by their fathers to believe that their education will allow them to escape all of the drudgery.

Granting that the ability to apply one's self to hard tasks is at least as important as education, is it exactly fair to allow our homes to be flooded with articles which lead ignorant parents to believe that their sole responsibility to children consists in keeping them in school?

Just a word of caution. If you believe that I am opposed to educating the young, please read again what I have written and be assured that I have not said so.

Lethbridge Coal Field Developing Rapidly

Seam Has Eight per Cent of Moisture and Though It Contains Only Four and One Half Feet of Clean Coal, Its Good Roof, Level Floor and Freedom from Water Make Mining Easy

BY JOHN H. TURNER
Lethbridge, Alta., Canada

LETHBRIDGE is the oldest coal-mining region in the province of Alberta, coal having been mined in that district for more than forty years. The Geological Survey of Canada (1914) is authority for the statement that coal was probably mined at Coal Banks (Lethbridge), Belly River, in 1874, the output being hauled by team to the barracks at Macleod. At that time the coal was excavated from the banks of the river; but, later, a company was formed and a plant erected, which caused the industry to assume greater importance. In 1886, prior to the advent of the railroad, coal was shipped down the river in scows.

According to Dr. Dawson, the coal measures in the Lethbridge district contain several associated seams, only one of which is of sufficient thickness to be worked. That seam was first mined in the banks of the river, the operation being known as the "Sheran mine." Subsequently, the Northwestern Coal Co. operated the same seam on the opposite bank of the river. For the sake of distinction, this will be called the main seam.

During the summer of 1882 the Sheran mine started a small level or drift. Both that mine and the Northwestern Coal Co.'s operation were located in Section 36, Twp. 8, Rg. 22, west of the fourth principal meridian, which is that indicated at the bottom of the accompanying map of the district. Since that time, from twenty-six to thirty mines have been opened in the area covered by the map.

SIX MINES PRODUCE MOST OF LETHBRIDGE OUTPUT

At the present time, twenty mines are being operated in this district, the more important being the following: Galt mine No. 3, capacity 800 tons a day; Galt mine No. 6, capacity 1,600 tons per day, both these mines being operated by the Canadian-Pacific Ry.; Federal mine with a capacity of about 150 tons per day, operated by the C. S. Donaldson Coal Co.; Coalhurst mine, capacity 1,200 tons per day, operated by the North American Collieries, Ltd.; Chinook mine, capacity about 400 tons per day, operated by the Chinook Coal Co. and Lethbridge Coal Co.'s mine with a capacity of from 150 to 200 tons per day. The other fourteen mines are operated at different points on the outcrop along the river bank and streams, but they supply local trade only.

The topography of the district is that of a gently rolling prairie, having an elevation ranging from 3,000 to 3,250 ft. above sea level. The soil is a rich loamy clay, and water is very scarce. As appears in the map, this prairie is cut through by the Old Man River, which is 300 ft. below the prairie level. The river has many branches, some of which extend miles back into the prairie. The river itself at times attains a width of over a mile.

The coal is found at the base of the "Pierre shales," in what is known as the "Belly River" formation. The following table is a typical section of the strata overlying the coal, which may be summed up briefly as

Boulder clay, 128 ft.; a glacial deposit of stratified material, 123 ft.; Pierre shales, 305 ft., beneath which are thin coal seams and shales overlying the main seam of coal. This main seam has an average thickness of 6 ft., but contains only 4½ ft. of good, clean coal.

A small quantity of water was struck in the moist river sand, at a depth of 190 ft., and again in the shales between 442 ft. and 480 ft. in depth. Little water is encountered in mining operations throughout the district.

In Table 2 is given the analyses of coal made recently by the Scientific & Industrial Research Council of the Province of Alberta, as given in its Report No. 5, 1922. The samples of coal analyzed were taken from five of the largest mines in the district. It is noteworthy that the results of these analyses show the coal to be superior to that of other lignite coals now being mined in Alberta.

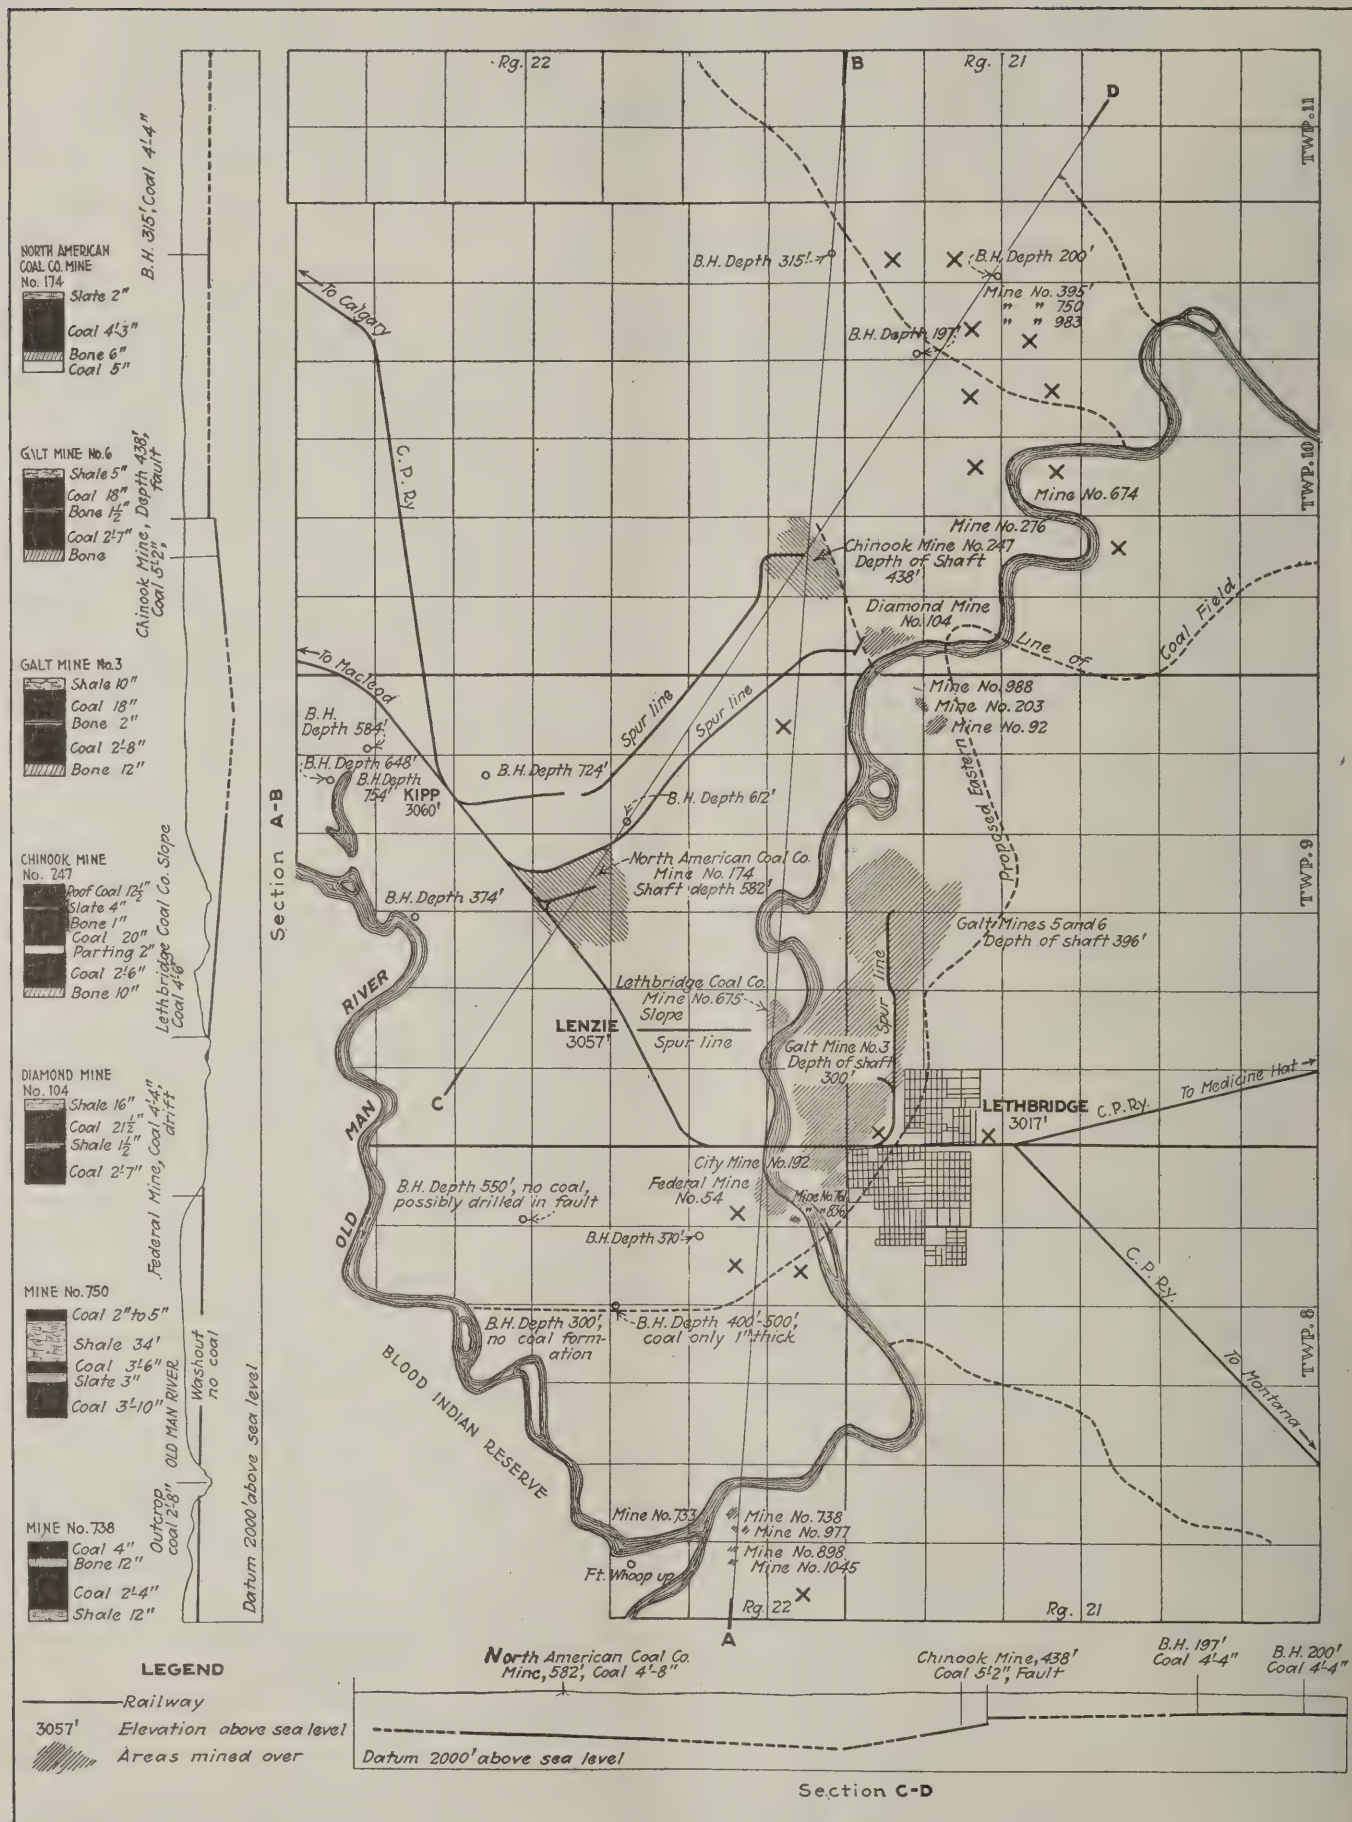

Though slightly undulating, this main seam has a general average dip of from 1 to 2 per cent in a direction varying from N 8 deg. W, to N 27 deg. W, according to the locality. In the southern and western part of the field the undulations conform to the average dip. The thickness of the seam decreases toward the southern and eastern boundaries of the field.

From present indications, it appears that there is a trough or valley that commences at or near the Southeast corner of Sec. 30, Twp. 9, Rg. 21, and extends approximately in the direction N 27 deg. W. It is possible that further exploitations to the North and west of the field may develop a basin in that portion. As indicated on the map by a dotted line, a well defined fault of 80 or 100 ft. lies between the Chinook and Diamond mines. This fault first was located in the former workings. The development there shows the seam to be dipping from 1.5 to 7.5 per cent, in a direction S 60 deg. W, along the northeastern edge of the trough or basin previously mentioned.

It is thought that a greater thickness of coal may develop in the lower levels approaching the center of the trough. An interesting feature of this seam is the generally uniform bearing of the cleats, in all the mines operating in the area shown on the map, as well as in mines to the north, east and south of this area. This bearing varies from S 61 deg. W to S 64 deg. W.

Principal Part of Lethbridge Coal Field, Alberta, Canada

Though the coal is lignitic it is of relatively high quality. As the field lies to the east of the Rocky Mountains and is level and almost untroubled, which cannot be said of the mines in the country to the West, the Lethbridge field has a distinct place in the geologic economy of the Province of Alberta.

There are many outcroppings of this seam, which I have indicated on the map by crosses.

The map covers only a portion of the whole area constituting the Lethbridge coal field, which embraces in all an area of 156,500 acres. Of this area, 108,000 acres contain merchantable lignite coal of superior quality. At present, little more than 3,000 acres, or 2.8 per cent, of this area has been developed in the forty years of coal-mining operations. In 1886 when, as already stated, coal first was shipped by scows from the Lethbridge field, the total output from the Province of Alberta was only 43,200 tons of coal, which increased to 1,246,360 tons, in 1916; and 5,976,432 tons, in 1922; and one-tenth of this total output then came from the Lethbridge field.

The report of the Mines Branch of the Province of Alberta, 1919, states that "over 100,000,000 tons of coal have been opened by mining operations, of which only 47,628,498 tons have been actually extracted; the remainder 26,628,770 tons have been lost beyond chance of recovery." The loss of coal mentioned in this report is a serious matter and worthy of the gravest consideration on the part of all concerned. Not only is it a waste of the nation's resources; but it is, also, a source of serious pecuniary loss to the mining industry of the province and is responsible, to a large degree, for the present high cost of coal.

Speaking from the standpoint of the coal operator, loss in extraction means a decrease in the value of assets. To open and mine a given area requires a certain expenditure for development and equipment. This determines the cost of these items per ton of coal mined. If half the coal is lost beyond recovery, it is evident that the return on the capital invested will be reduced 50 per cent. Incidentally, the overhead charges will be proportionately increased and the expense of haulage, drainage and ventilation per ton of coal mined will exceed the normal cost. So down the whole line of expenditure there is an increase in cost, while the income that should be available is reduced, which proves the necessity of enforcing economies in the system of mining with a view of producing cheaper coal.

ADVANTAGES POSSESSED BY LETHBRIDGE FIELD

The Lethbridge field is possessed of several advantages which reduce the cost of mining. Little or no water is encountered in sinking and in the development of the underground workings. Little or no gas is present and practically all the small mines use open lights. One of the large mines in operation for many years, still adheres to the open-flame lamps, others of the larger mines are equipped with electric cap lamps or flame safety lamps. The conditions of roof and floor are fair, which means economy in timber and the cost of upkeep of roads and air-courses.

In general, the mines of the district are worked by some form of the room-and-pillar system. Though on several occasions, modified longwall has been tried without success, it does not follow that longwall is unsuited to the mining of this coal. Eventually, some form of longwall may be found that will be better adapted to the conditions in the district than any yet tried.

Main roads are driven on the face of the coal, two, three and four abreast, at distances of 1,100 or 2,200 ft. apart. From these face entries, butt headings are driven in pairs, 400 or 500 ft. apart. The butt headings are driven to the right and left of the main entries and rooms, from 12 to 30 ft. wide, are turned off each

Table II—Analyses of Coal at Lethbridge, Alta, Canada

pair of butts and driven to meet similar rooms driven from the adjacent butts. The width of rooms and room pillars will vary considerably, the distance, c. to c. ranging from 35 to 46 ft. As quickly as rooms are completed, the room pillars are drawn back, the entry pillars and stumps being removed as each pair of butts is finished.

Compressed-air punching machines are used for undercutting the coal. In some cases, the coal is sheared in the center, with the result that a larger percentage of lump coal and less fine coal and slack is produced. Permitted explosives are employed for shooting the coal. In the smaller mines, horses are used to haul the coal from the face to the shaft bottom. In the more extended workings, horses are used only to gather the coal, which is hauled out of the mine by an endless rope.

HOW SILICA AIDS TUBERCULOSIS.—Dr. W. E. Guy and Dr. W. J. Purdy have been engaged at the National Institute for Medical Research, Hampstead, Eng., in the study of the poisonous properties of colloidal silica, hitherto believed to be harmless. With Dr. E. H. Kettle Dr. Guy has completed and published studies of the effects of silica dust upon the tissues with special regard to the problems of industrial tuberculosis. These inquirers have made a thorough investigation of the experimental basis of the treatment of tuberculosis with soluble silica, which some have recommended. They have found says the *Colliery Guardian* that colloidal silica fed to or injected intravenously into susceptible animals has no influence on the progress of tuberculosis; the only effect it has is to localize the infection where the lesion caused by silica—soluble or insoluble—is such as to provide a *nidus* in which the tubercle bacilli, protected from the bactericidal defenses, possessed by the normal tissues, can initiate progressive damage. Thus a small dose of bacilli given with silica becomes in effect a large one, and the infection becomes firmly established.

TRAPPING FLAT PIECES OF SLATE—Screens and rollers have been installed in Great Britain with corrugated surfaces. These set flat pieces of material on edge, thus allowing them to pass through holes edgewise, the rounder pieces passing over the top of the corrugations or on the top edge of the rolls. This effects a separation of shaly material from the rounder coal. The separation was not complete so far as the shale and small coal was concerned, but it insured the larger coal being practically free from loose shale and the extracted mixture containing a large percentage of rock could be dealt with by other means.—Cecil Bentham at the meeting of the Manchester Association of Engineers.

Deputy Chief Walker Describes British Mine Laws, Emphasizing Points of Difference

Firebosses Inspect Places for Gas Three Times Daily—Timbering Methods Prescribed by Division Inspectors—Inspect Mines by Sample—More Dangerous Mines More Frequently Visited—Thorough Wetting Costlier than Rock Dusting

QUANTITY of air rather than quantity, regulation of timbering by the inspectorate, and instruction of mining novices by experienced men are three important features in the British mining law which Henry Walker, deputy chief mine inspector, Great Britain, described on the evening of March 4 in an address on "Engineering and Safety Problems of the Coal Mining Industry of Great Britain," at a joint meeting of the civil section of the Engineers' Society of Western Pennsylvania, the Pittsburgh section of the American Institute of Mining and Metallurgical Engineers and the Coal Mining Institute of America.

Mr. Walker described those details of regulation in the Coal Mines Act of 1911 which differ most from those in force in the United States. A fireman (fireboss) must examine all places in his district before his men go to work. Twice during the shift, in the morning and afternoon, he must make a like examination. Mr. Walker believes more firemen should be employed and the mines divided into smaller districts. By such means, he believes many accidents will be prevented, especially those resulting from roof falls.

Col. Edward O'Toole, general superintendent of the U. S. Coal & Coke Co., has a similar point of view. His success in reducing accidents by dividing a mine into small districts under the supervision of assistant mine foremen was detailed by Howard N. Eavenson at a meeting later in the week.

MUST WORK TWO YEARS UNDER EXPERIENCED MAN

In England unskilled workmen must work for at least two years under the direction of skilled miners, at the end of which time they are rated as "experienced" men. No skilled miner is allowed to supervise the work of more than one novice.

"Half of our accidents are caused by falls of roof," Mr. Walker remarked. "Consequently, all working places are required to be adequately supported by rows of posts or chocks. The intervals at which these are spaced usually are specified by the division inspector. As a rule, the intervals are less than those allowed in the United States. The row of supporting timber must be placed no less than 4 ft. from the face."

An "agent," one who represents a coal company and is superior to a mine manager, must have the same qualifications as the latter, if he has any authority as to the manner in which the mine is conducted. That is, he must hold a first-class certificate. While this might work a hardship on a number of our higher coal-company officials, such an act in this country would prevent not a few mine disasters.

Mr. Walker said that in Great Britain the mine ventilation must be adequate to give the right "quality" of air regardless of volume. S. A. Taylor reviewed the origin of those provisions of the mining law of Pennsylvania relating to the quantity of air required for ventilation. At that time, it was held that the

average man breathed 9 cu.ft. of air per minute. A margin of safety was established by requiring enough air to be pumped into non-gaseous mines to furnish 100 cu.ft. of air per minute to each man, and in gaseous mines, twice that amount. In late years this margin has been increased.

Mr. Taylor said he believed that quality should come before quantity, contending that air at a high velocity stirs up coal dust, increasing the risk of an explosion from this source. George S. Rice, of the U. S. Bureau of Mines, said that lessees of government-owned coal lands in the west must comply with a federal law specifying "quality" in ventilation.

The discussion then turned to the regulation of hoisting equipment. Prof. Fred Crabtree asked if hoisting equipment was examined every week. Mr. Walker said that it is examined daily. That the English law is one-sided in this regard was revealed in the answer given Graham Bright's interrogation as to what precautions are taken to control a hoist, should its operator suddenly become incapacitated. Regulation covers only precautionary overwinding equipment. Safety catches are not used to stop a cage in the event the rope breaks. Prevention of accidents from this source is dependent upon rope inspection.

WILL COLLABORATE IN SAFETY INQUIRIES

A spirited mine-safety conference was held all day, March 6, in the assembly room of the Pittsburgh station of the U. S. Bureau of Mines. A. C. Fieldner presided. Dr. H. Foster Bain, Director of the Bureau of Mines, outlined the purpose of the British representatives in coming to this country: To promote the proposed international co-operative research into safety in mining which they themselves had proposed. Dr. Bain hopes that each country will manage to send representative research men to the other's experimental stations to form a close contact in the work planned by the two organizations.

"The Mines Inspection Department of Great Britain" was the subject of a talk by Henry Walker dealing with the organization and duties of the department of which he is the head. Inspections of mines are made without notice. Contrary to the American practice, an English inspector is not required to examine all parts of a mine. Usually he visits one section and takes its condition as a criterion of that of the entire mine. If suggested corrections are not made between visits of an inspector, the Mines Inspection Department may delegate two inspectors to make a joint inspection of every working place in the mine.

Failing to observe the recommendations made after the joint inspection, a mine manager is liable to prosecution. This action, however, is seldom taken. In case of difficulty in his problem, the mine manager takes the inspector into his confidence and seldom tries to hide trouble. In turn, the mine inspector co-operates

with him to remedy faults and does not resort to the alternative of prosecution.

In order of rank, the staff of the Mines Inspection Department consists of a chief or deputy (Mr. Walker) and division senior, junior and sub-inspectors. A division inspector has duties and responsibilities on the plane with those of our state mine inspectors, and he may be provided with one or two clerks and an office. Vacancies made by the promotion, retirement or death of division inspectors are filled by competitive civil-service examinations.

Promotion is made on merit and not on seniority. A retiring inspector receives a pension equal to one-sixtieth part of his yearly salary for every year he has served, or he may accept a lump sum equal to a year's salary plus one-eightieth of that earned for every year in service. He may retire with pension at 60 and he must retire on reaching his sixty-fifth year. Salaries are low, and allowances for expenses in traveling are less than actual expenditures.

Miners have the prerogative of appointing two fellow workmen to inspect the mine in which they are employed. Miner inspectors may be delegated to make only one examination of the mine or they may be appointed for a term. In either case, the workman must pay the wages of his representative inspectors. At the end of each day these men must file a report with the management. The managers must submit any unfavorable report to the division inspector. The system gives the miners confidence in the safety of the mine in which they work. J. W. Paul inquired as to the extent of labor turnover in British mines. Mr. Walker said that it was very small. The miners are little disposed to wander from mine to mine.

MINES EXAMINED BY SAMPLE AND WHEN NEEDED

Mines are not inspected on any regular schedule. Those in which dangerous conditions are found are examined more frequently than others. In answer to a question by George S. Rice, Mr. Walker said that the inspector's report was not posted at the mine. "No one," said Mr. Walker, "outside of the inspection department had a right to see this report." When asked his opinion as to the policy of posting reports as is customary in the United States, he replied, "The posting of a report publicly proclaims the inspector's rating of the conditions of the mine at the time of his examination, and may not be a correct statement of the conditions existing ten minutes or ten days later." He does not favor the practice of posting reports. An inspector should not be held responsible for accidents occurring in a mine soon after it is examined, and certainly not at a later period. It was argued, however, that the posting of an inspector's report inspired the miners with confidence.

"Research on Mine Explosion Prevention with Special Reference to Stone Dusting" was the subject of a talk by Dr. R. V. Wheeler, Director of the Department of Mines of Great Britain. In that country, researches are being made to discover something more effective than stone dusting in preventing dust explosions. Coal dust presents a peculiar problem because a small fraction of the quantity usually distributed on the roof, ribs and floor of the mine is sufficient to propagate flame. The rôle of inflammable material in diluting coal dust is parallel to that which ventilation plays in diluting firedamp. Though Great Britain is still studying the action of coal dust under various conditions and

Administration Building, Carnegie Institute of Technology, Pittsburgh

The Carnegie Institute welcomed the delegates from England to its auditorium. The Institute recognizes that it can afford no greater service to the industry than to promote aggressively the campaign for safety in mining. The mine operators and managers are looking askance at the frequency of big explosions and wondering if their fate, misfortune or destiny it is to be the next victim.

is hunting industriously for a substitute, it has decided to rely upon the ability of rock dust to prevent explosions until a better means has been found. Dr. Wheeler is particularly anxious to drive home this purpose, as is evidenced by the fact that he repeated it several times in his series of talks in Pittsburgh.

Included in the study of the ignition of coal dust, three problems have received much attention: (1) The character of coal dust; (2) the character of the mine atmosphere, and (3) the character of the source of ignition. The last problem involves studies of sources of ignition both of short and long duration.

In studying problems relating to the propagation of coal dust explosions, four major factors are given careful consideration. These are: (1) the maximum degree of violence such an explosion can acquire; (2) the effect of restrictions in a roadway (causing turbulence and increasing violence); (3) the effect of air currents on the characteristics of an explosion; (4) the effect of the position of the source of ignition. These are being studied in the attempt to find something to supersede rock dusting, and are not being made because any doubt exists as to the value of following that practice at the present time.

LIGHT-COLORED DUST CONSERVES ILLUMINATION

George S. Rice and Edward Steidle spoke on "Rock Dusting or Stone Dusting as Applicable to American Mining Conditions." Mr. Rice reviewed British methods prior to 1920 when the official law relating to rock dusting was inaugurated and then turned his attention to the practices in the United States. Light-colored rock dust should be used, not only because it aids in underground illumination but also because it enables one to judge with surprising accuracy its percentage in a mixture with coal dust.

The shortcomings of water as an agent to make coal dust harmless compel us to look for a substitute. None better than rock dusting is known. At present only two or three companies in the United States are using this system, but sooner or later the practice must become national. Mr. Rice did not infer protection by rock-dust barriers but by the English method of general distribution of rock dust throughout the mine. The coal-dust hazard, he added, is more serious in this country than in England.

There, practically 90 per cent of mining is longwall

and few of the coal seams are developed by entries, thus avoiding the explosion hazards of narrow places. In this country the thickness of exposed coal is in most cases equal to the height of the entries. The spalling of exposed coal, the absence of rock spillings, the building up of coal in the sides of mine cars and the rapidity of haulage combine to intensify the hazard of coal dust as compared with that in England. Mr. Rice frankly admitted that he has no confidence in any method of watering or humidification, because explosions had occurred in mines which took pains to be thorough in the use of water or steam. He is inclined to believe that rock dusting is cheaper than any system of wetting or humidification that rightly may be termed thorough.

ROCK DUSTING SHOULD BRING LOWER INSURANCE

Captain Steidle took the operator's viewpoint in the matter. If rock dusting is cheaper than present practices with a like purpose, then it should be adopted without hesitation. New operations should be protected by it from the start. Compensation insurance ratings ought to be reduced for those mines which use rock dust. "Solid" mine cars and rotary dumps eliminate much of the dust on roadways.

The morning program wound up with a general discussion, started by Dean Holbrook who was interested in the milling and screening of rock dust. Mr. Rice explained that the Griffin roller mills are used more generally in Great Britain than grinding machines of any other type. The hammer-head type is better in the opinion of Dr. Wheeler. He urged that care be taken to detect the wearing of the screens, which, when it occurred, prevented accurate sizing. Centrally located mills on a joint ownership basis will probably be established in the United States. The most important questions for consideration, according to J. T. Ryan, are what materials should be used and how fine they should be ground. The arrangements for grinding are of secondary consideration.

CARBONACEOUS SHALE SHOULD NOT BE USED

Mr. Rice added that shales containing much carbonaceous material should not be used for two reasons: (1) Because the quantity required will be greatly in excess of the quantity needed where carbon-free shale is used, and (2) because the carbonaceous shale does not reflect light as effectively as pure shale or limestone.

Richard Maize asked if water will be used in connection with rock dusting. Mr. Rice replied that it should continue in use, for thereby the air currents will be prevented from carrying coal dust. In Alabama a number of cutting machines are equipped with spraying devices. S. E. Reynolds believes most explosions would not occur if coal dust did not spread. In response to a question by Mr. Maize, Mr. Rice said that though the hand method is probably best, the high labor cost of that method of distribution would inevitably lead to the use of machinery in its stead.

When R. Z. Price asked where rock dust should be spread, Dr. Wheeler suggested that it be placed wherever coal dust occurs. It should be mixed with coal dust in rooms and extended to the face.

The Inland Collieries Co. is beginning to use rock dust in its Indianola mine. T. G. Frear, general manager of the company, related in a few words the steps he is taking. Shale dust injected into entries displaces coal dust on the roof and ribs. A period of four hours

is required for the dust to settle. Some of the dust traveled half a mile. Earlier in the discussion Dr. Wheeler said he attached little importance to the portability of rock dust in air currents.

In next week's issue of *Coal Age* the discussions of the Mine Safety Conference will be concluded by an account of the afternoon session.

Moments of Unusual Danger from Falls

MINING men in America have thought that they noted that at a certain period of the night the danger of falls increased. Unfortunately no one in the United States appears to have made any effort to sustain that belief from reasoning or definite observation. Men are not working in equal numbers night and day, and so statistics of accidents from falls are not evidence of the hazard. In fact, the accident record would tend to prove the night the less hazardous if we did not know that at that time few persons are exposed to the risk.

D. W. Rees in an article in the *Colliery Guardian*, Vol. CXXV., p. 331, recently regretted that more attention had not been given to this subject, seeing that falls in the aggregate killed and maimed more men than explosions. He explains that the earth tilts on an average twice a day and in winter sometimes more often. That tilting is only about one-thirtieth of a second of arc but this, though intrinsically small, corresponds to a vertical movement of the strata of about 60 ft. The figure given is often exceeded, however. One or two hours after midday or midnight is the most likely time to observe this effect.

Mr. Rees declares that miners know as a matter of tradition that a visible and audible effect is produced at these times and that falls which are on the point of occurring are most likely to take place during those periods. He says that fine matter drops from the roof at these intervals, showing that a slight movement of the strata as a whole is taking place, a grinding noise is heard as the roof settles on the packs, and the mine seems to be moving in every part. The greatest effect over a period is produced in March and September, but weighting should proceed at a more rapid rate in winter than in summer.

The author shows a chart showing the relation between the number of unassisted falls and the time of occurrence averaging over the period of one year in a seam with a weak roof. From this can be gathered that an average of fourteen and a half occurred at about 2:30 a.m. and six about 2 p.m. These periods were the two maxima. The night maximum, though higher than the day maximum, is of a duration not in accord with its intensity.

At midnight, about 0.5 falls occurred; at 2 a.m., about nine; at 2:30 a.m., as stated, about fourteen and one half; at 3 a.m., about twelve; at 4 a.m., about six; at 6 a.m., only three; at 8 a.m., less than two; at 10 a.m., a little less than one. Then starts the day maximum. At noon there are two and at 2 p.m. there are, as stated, six; at 3 p.m., about five and a half; at 4 p.m., only three, and thereafter till midnight, never more than one and a half nor less than one half. The author does not state the length of time taken as the basis for these figures, whether a day, a week or a month, nor the size of the mine. He only states that they are averages for one year.

Determining by Volumetric Tests the Quantity of Unmarketable Material in a Coal Seam

Displacement Tank Used to Obtain Volume of the Various Sizes of Coal Shipped—Volume of Coal in Solid Calculated from Mine Maps and Compared with Volume Shipped to Market

BY HAYDN OWENS

A PRACTICAL example of how the mining engineer devises schemes for assisting him in his work occurred when the problem of determining the proportion of waste coal in a certain mine area presented itself to our department. The mine maps were first carefully measured by means of a planimeter, and by applying the thickness and pitch factors, the total number of cubic feet of coal removed from the section was determined. The total tonnages of the various sizes of coal mined and shipped from the area were next obtained, and by means about to be described, their volumes were ascertained. Obviously, the volume of the waste or unmarketed coal must be equal to the difference between the volume of coal originally in the section and the volume of the coal mined and shipped.

DISPLACEMENT TEST MADE OF PRODUCT IN BULK

The real problem in the investigation was the determination of the volume of the coal which had been marketed. Knowing the tonnages of the various sizes of coal shipped and by combining with it the academic principle of water displacement the solution became quite simple.

When a solid body is immersed in water, the volume of water displaced is equal to the volume of the body itself, and by the application of this basic principle we found a means for determining the volume of the coal which had been shipped to market.

The water displacement test was made in a tank which consisted of two uncovered compartments connected by a pipe. If the time consumed in making the test covers an extended period and the material tested is heavy the tank should be lined with sheet iron or constructed of concrete, thereby preventing the interior from becoming worn, and thus enlarged. Should this wear occur, the accuracy of the test would be destroyed. If the material to be tested is not heavy and not liable to injure the sides or bottom of the tank, it may be constructed of wood. In this event well seasoned red cedar, cypress or white pine should be selected. The surface of the wood should be well shellacked and painted, and all joints should be carefully calked to prevent losses by absorption and leakage.

The accompanying illustrations show a well-constructed wooden tank suitable for testing light materials. It is made with a displacement compartment *A*, the bottom of which is lined with sheet iron. A measuring compartment *B* connected by a pipe *C* and holes at *D* and *E* for draining off the water. Each compartment is 3 ft. square, the water flowing from the displacement compartment to the measuring compartment at a point 4 ft. above the bottom of the tank. Therefore, each compartment will hold 36 cu.ft. of water.

To explain the method of conducting a test we will

assume that we desire to determine the volume of a known weight of chestnut coal. After inserting the plugs at *C* and *D* (Fig. 1) the displacement compartment *A* is filled slightly above *C*. When the plug at *C* is drawn, the water drops to the lowest level of the pipe, to wit, 4 ft. above the bottom of the compartment. After the excess water has passed to the measuring compartment and out at *E*, the plug at *E* is inserted and the tank is ready for the test.

Fig. 2 shows a 1,000-lb. sample of chestnut coal which has been dumped into the displacement compartment, its equivalent volume of water having passed into the measuring tank. It is now necessary to determine the volume of the water thus displaced. The depth of the water is measured and found to be 1.18 ft., and the bottom of the tank being 3 ft. square the volume of the water must be 10.62 cu.ft.; therefore 1,000 lb., the weight of the coal, divided by 10.62 gives the weight per cubic foot of the chestnut coal as 94.16 lb. in the solid.

STEEL TAPE BETTER THAN ROD FOR MEASURING

Care should be taken in establishing the depth of the water in the measuring tank, because capillary attraction will cause the water to rise up the sides of any measuring rod that is inserted in it. A good device for this purpose is a steel tape with a plumb bob suspended from a board *F* to the surface of the water, the depth of water being determined by the difference between the distances of the board *F* from the bottom of the tank and from the point of the plummet respectively. To aid the eye in discerning when the plumb-bob point reaches the surface of the water a small quantity of fine dust may be sprinkled over the surface.

To the total tonnages of the various sizes of coal shipped was applied the weight per cubic foot of the respective sizes. This gave the solid content of the coal

Fig. 1—Isometric View of Displacement Tank

Compartment *A* is first filled so as to overflow through pipe *C* into compartment *B*. This establishes the proper level in *A* making the tank ready for the test.

Fig. 2—Making a Volumetric Test of Coal

The coal in compartment A has displaced a quantity of water equal to its volume. The level of the water in compartment B is measured by means of a plumb bob and measuring tape. The height of the water in the tank is equal to the depth of the tank minus the distance measured by the tape as shown.

removed. The difference between the volume of the original coal area in the mine and the volume of the coal shipped gave the volume of the waste.

In Its Coal Era, South Wales Was Folded, Like Pennsylvania, in Two Directions

BY R. DAWSON HALL

Engineering Editor, *Coal Age*

BROADLY speaking, the history of folding movements during the laying down of the Carboniferous measures in Pennsylvania and South Wales has some points of similarity. In South Wales, anticlines and synclines in two different directions may be found. Some run northwest and southeast and some east and west. The latter in South Wales attain "considerable magnitude and at the present time" say Davies and Cox in a paper presented to the South Wales Institute of Engineers "determine the dominant features of the coal field." The two classes of folds appear to have been formed promiscuously, now one now the other. The forces causing one class of fold apparently ceased to act and the forces causing the other came into play only to be replaced later by thrusts accentuating the first folds or perhaps starting others in the same direction.

In Pennsylvania also there are flexures in two directions and it seems probably they alternated, or as Mr. Davies would say, they "oscillated." No expressive word seems available for the relative occurrence of these intermittent, interacting and irregular impulses. One series of Pennsylvania folds has a northeast and southwest trend instead of northwest and southeast as in South Wales. That series is the dominant geological feature. There is also a series running east and west. It is distinctly subordinate to the other and is certainly not the dominating series as is the east and west folding of South Wales.

In speaking about that principality Davies and Cox remark that the later movements might be expected to cause an apparent deflection in the axis of an earlier movement. It might also cause a local thickening to be superposed on a local thinning where to a synclinal axis would cross an earlier anticlinal axis or conversely a local thinning to be superposed on a local thickening due to a later anticline crossing an earlier syncline. However, they say that they are not prepared to state whether this thinning and thickening action is marked enough to be of commercial importance.

Another instance of the value of the displacement test occurred when it became necessary to estimate the capacity for water storage of a partially inundated quarry, conditions being such that it was not easy to survey the area owing to the difficulty of obtaining access to the excavation. In this case, to the record of loose shipments the data obtained from the displacement tests was applied converting the loose material removed into cubic content in the original solid and so the storage area was ascertained.

It would be possible to determine the specific gravity of solids by dividing the weights per cubic foot by the weight of a cubic foot of water. This, however, is not recommended, as only a sensitive balance should be used for this purpose, and the voids in a coal pipe are different for various sizes of coal.

In making a test of coal shipped to market in the manner just cited, the percentages of impurities carried by the coal should receive consideration. The coal should be graded either to conform to the trade allowances or to the averages of the percentages obtained in the tests made by the coal inspector.

By numerous measurements the authors have made maps showing where the intervals between coal beds are of equal thickness. These lines they term isopachytes. They found sometimes in the higher seams a little difficulty in correlating the beds. Therefore pending a more reliable correlation of the seams between the Two-Foot-Nine and Rhondda No. 2 seams it has been found advisable to utilize only certain of the more prominent seams such as the Two-Foot-Nine, Rhondda No. 3 and Rhondda No. 2. Thus in all seven isopachyte maps have been prepared, five of which show the variation in the thickness of the intervals of the strata between the following horizons: Rhondda No. 2, Rhondda No. 3, the Two-Foot-Nine, the Four-Foot, the Six-Foot and the Nine-Foot seams.

It would not serve the interests of the readers of *Coal Age* to go into the details of these variations in thickness of interval. It would seem better rather to point out that this study should be pursued with regard to the coal measures in the United States as much of value geologically would be discovered. There are evidences in plenty of east-and-west synclines in the Kittanning measures and of anticlines which run in the same direction. The buried rivers of the Kittanning period are also more or less of east-and-west trend. The coal in the Middle Kittanning is often found only in such synclines and it rapidly thins as the bottom of syncline is left.

In the Freeports, strange to say, the evidences as of these synclines and the thickening that goes with them is not evident, making it questionable whether the thrust north or south whichever it was continued into the period when the Freeport was laid down. Perhaps as in South Wales it did not persist. This inquiry into the South Wales field would furnish a suggestion for geologists, striving to trace the history of the deposition of our beds, to forecast the direction of the main buried valleys in the Freeport and Kittanning horizons and also to prognosticate the areas in both groups of beds likely to be found most productive of coal. The study may be easier later when the ground has been better proved but it certainly then will be less productive of valuable results, for when the coal is out the indications will have only academic value.

News Of the Industry

Central Pennsylvania Coal Miners Seek Best Scale Obtainable for Three Years

The convention of District No. 2 (central Pennsylvania), United Mine Workers, came to a close March 22, when it was agreed that the scale committee be authorized to obtain the "best agreement obtainable as to wages and working rules on the basis of no wage reductions and for a period of three years." It also was agreed that the salaries of district union officers be increased and that the *Penn Central News*, the official organ of the district union, be abolished. The convention lasted two weeks, and most of the sessions were stormy. Representatives of the miners and operators will meet to negotiate a wage agreement in Philadelphia this week.

The proposal to increase the salaries of district union officials was overwhelmingly defeated on the first vote. On reconsideration strong pressure was brought to bear on the delegates, it being set forth that living conditions and expenses have undergone such changes since the present wages were adjusted that it was no longer possible to make ends meet. When the vote was taken the second time it carried, 441 to 320. The salaries hereafter will be as follows: President, \$300 per month, an increase of \$75; vice president, \$275 per month, an increase of \$75; secretary-treasurer, \$300 per month, also an increase of \$75 per month. Board members will receive \$250 per month, an increase of \$56.

Strike Was Costly to Union

The scale fixed for checkweighmen was fixed as follows: From 25 to 200 miners, \$7.95; 201 miners and over, \$8.50. A resolution also was passed which provides that any member of the union found guilty of assisting any mine foreman to discriminate against an active member of the organization shall be fined \$100 for the first offense and for the second offense shall be expelled for two years and fined \$200.

The report of Secretary Richard Gilbert, which was accepted and ordered filed, shows that the strike in Somerset County, which terminated last August, cost the district, from April, 1922, to December, 1923, \$1,186,915.17.

A long list of resolutions was adopted, of which the following is a brief résumé: Favoring the creation of a permanent national fact-finding agency for the industry; endorsing the work done by President Brophy in forming a plan for public ownership and democratic management of mines; to have asthma classed as an occupational

disease; demanding that shotfirers in gaseous mines possess a state certificate and be able to read and speak English; to have the union employ physicians; that the district officers take out compensation for all local officers and delegates when they attend conventions, and requesting approval by the district officials of all national organizers and field workers sent into the district.

The report of the scale committee was adopted, after being fully explained by President Brophy, during which he declared that all grievances will be taken up at the conference with the operators in Philadelphia and that the union will go the limit to improve working conditions. The report as adopted reads:

"We, your scale committee, recommend to the convention, in lieu of all resolutions relating to wages and working conditions that have been presented, that the scale committee of District No. 2 be authorized and instructed to secure the best agreement obtainable as to wages and working rules on the basis of no wage reductions and for a period of three years.

"The scale committee is authorized to take such action for the protection of our best interests as circumstances may require, and to advise the membership of unexpected developments that may arise and which cannot be foreseen."

The scale committee is composed of John Brophy, Richard Gilbert, James Mark, William Welsh, Patrick McDermott, Harry Crago, H. Elmer Johnson, F. V. McCloskey, Arthur Taylor, Leonard Cluiois, Herman E. Varletto, George Mottey, Peter Ferrara, James H. McCarthy, William Ackley, John P. Nelson, Tony G. Badiale, D. P. Kirk, S. J. Hudunski and William Hoskins.

DuBois was selected as the meeting place for the next convention.

Heavy Union Majority for Jacksonville Agreement

The three-year wage agreement negotiated at Jacksonville last month for the Central Competitive Field will be accepted by an overwhelming majority, according to an announcement at headquarters of the United Mine Workers, Indianapolis. Several days more will be required before all the ballots have been returned and tabulated.

John L. Lewis, president of the miners' union, announced the international executive board would meet April 3 to consider routine matters.

Wyoming Signs Up

The United Mine Workers of America, District 22 (Wyoming), signed an agreement providing for a three-year extension of the existing wage contract without change as to rates or conditions, at Cheyenne, Wyo., March 19. The miners' union had about sixty delegates in session at Cheyenne from March 3 to 19 formulating demands for changes in rates and conditions regardless of the fact that their national organization at the Jacksonville convention and thereafter had approved a renewal of the existing contract without change for three years. The cost of the Cheyenne convention represented a heavy tax on the local unions.

11 Companies Join Coal Field Superpower Plan

Eleven electric-power companies controlling forty stations in five states, capable of developing 2,000,000 hp. and representing a capital of \$315,000,000, have joined in a co-operative distributing system to be known as the Coal Field Super Power Group, according to an announcement March 20 by H. Hobart Porter, president of the American Water Works & Electric Co. The group serves a population of nearly 8,000,000 people in the industrial center of the country embraced in Ohio, Pennsylvania, Maryland, Virginia and West Virginia.

Companies in the co-operative system include the Duquesne Light Co., Penn Public Service Corporation, Potomac Edison Co., American Gas & Electric Co., Cleveland Electric Illuminating Co., Ohio Public Service Co., Penn-Ohio Electric Co., Northern Ohio Traction & Light Co., Penn Central Light & Power Co., Keystone Power Corporation and West Penn Power Co.

Mr. Porter said the cost of electricity would be reduced by many millions annually and better service assured. Labor troubles also would be minimized, he said, for the coal miner would be provided steady work.

This particular superpower group is but one of many growing up in the country. The idea is taking hold in New England, New York, New Jersey, the South, the Middle West and on the Pacific Coast. The importance of the industries served in Ohio, Pennsylvania and Maryland has hastened the completion of plans there, but Mr. Porter stated it as his opinion that eventually all electric power in North America would be linked into one gigantic unit.

Settle Working Conditions but Not Wages at Baltimore

Operators of northern West Virginia and the United Mine Workers had agreed on working conditions but not on a wage scale when the conference at Baltimore adjourned Saturday, March 22, to reassemble Wednesday, March 26.

George C. Brackett, executive vice-president of the operators' association, however, expressed confidence that complete agreement would be reached between the miners and operators after going back home to talk it over.

"All changes agreed upon as to working conditions," Mr. Brackett said, "will tend to more efficient production of coal, better management of the mines and better understanding of the rules by both parties."

Coal Exporters Protest Low Rates on U. S. Ships

Exporters of coal have joined with shippers of certain other commodities in protesting against the action of the U. S. Shipping Board and the Interstate Commerce Commission, which will allow Sec. 28 of the Merchant Marine Act to become effective May 20. Under that act, the lower rates which are allowed on goods intended for export or on shipments being imported are to be applied only when the consignments are carried on ships flying the American flag.

Since the enactment of the Merchant Marine Act in 1920, the Shipping Board has not regarded the supply of American flag ships sufficiently adequate to justify the application of the provision. The Shipping Board is of the opinion, however, that "adequate shipping facilities now are available to handle the transportation of all commodities, other than grain, between ports of the United States and ports of Great Britain and northern Ireland and the Irish Free State, the ports of Continental Europe north of and including Bordeaux and the east coast of Asia, the islands of the Pacific Ocean, Australia and the East India islands and the ports of Central and South America."

Keeney Acquitted After Trial Lasting Five Weeks

C. F. Keeney, president of District No. 17, United Mine Workers, was acquitted March 15 after being on trial since Feb. 11 charged with having been an accessory before the fact to the murder of John Gore, a deputy sheriff of Logan County. The jury deliberated just an hour and a half before returning its verdict of not guilty.

In the closing hours of the trial it was apparent that the defense relied for acquittal on the evidence it had introduced to show that Keeney acted in good faith when he urged the miners in a speech at Madison to turn back, and that the state relied on the evidence it had introduced to show general

E. J. McVann

Attorney for the Fairmont operators in the Pittsburgh rate case, which will be reopened before the Interstate Commerce Commission April 22.

responsibility for the march as a means of obtaining a conviction.

It has not been definitely determined just which one of the defendants will be tried next. Charges still pending against Keeney include treason, of being accessory to the murder of John Cafalgo and two charges of insurrection. Several charges also are pending against Blizzard. Although Fred Mooney is under indictment with other union officials for alleged complicity in the armed march, he has never been brought to trial on any of the charges pending against him.

Deepwater Co. Buys More Alabama Coal Lands

Several hundred thousand acres of coal and iron lands have been acquired by the newly organized Deepwater Coal & Iron Co. in Cherokee, Marshall, DeKalb, Jackson, Fayette and Tuscaloosa counties in addition to the 500,000 acres already acquired in and near the Birmingham district by the company, according to an announcement by L. B. Musgrove, an official of the company.

This makes the company the second largest in the South in point of holdings and brings the total amount involved in the big enterprise to more than \$30,000,000, he asserted.

Engineers for the Robert W. Hunt Co., of Chicago, will prepare plans and specifications for the developments, mining, construction, building, engineering, etc. This Deepwater enterprise is a Delaware corporation, with an authorized capital of 10,000 shares of 7 per cent cumulative preferred stock of \$100 par value, and 200,000 shares of no par value common stock. L. B. Musgrove, of Jasper, is chairman of directors; Charles A. Meade, of New York, president; John M. Goetchius, Walter Douglas and Morris R. Poucher, of New York, vice-presidents; Charles T. Lark, of New York, secretary-treasurer and counsel.

To Study Operating Problems At Cincinnati Coal Show

A series of discussions of practical operating problems has been arranged in connection with the exposition of coal-mining equipment and machinery to be held by the Manufacturers' Division of the American Mining Congress at Cincinnati May 12 to 17. The coal symposium will last four days, beginning May 13; the program, which was arranged by Ralph C. Becker, Alphonse F. Brosky and H. F. Peck, follows:

"Problems of Mine Electrical Men," Graham Bright, chairman—(1) "Storage Batteries on Cutting Machines and Main-Line Locomotives," R. L. Kingsland; (2) "Advantages of Multiple-Speed Fan Motors," A. B. Kiser; (3) "Savings in Power and Maintenance by Better Voltage Regulation," Carl Lee; (4) "Economy of Equipment Standardization," J. H. Edwards; (5) "Inspection of Electrical Equipment," C. L. Harrod; (6) "Testing of Electrical Equipment," J. F. MacWilliams.

"Necessity for Rock Dusting," D. W. Buchanan, chairman—(1) "Occurrence, Characteristics and Behavior of Coal Dust," J. W. Paul; (2) "Actual Experiences with Rock Dusting," D. W. Buchanan; (3) "Tried Methods of Applying Rock Dust," John E. Jones; (4) "Methods of Procedure," John T. Ryan; (5) "Rock Dust vs. Water," Edward Steidle; (6) "Co-operation of U. S. Bureau of Mines," George S. Rice.

"Safety and More Lump Coal by Proper Use of Explosives," H. C. Adams, chairman—"Tests to Produce More Lump Coal," C. W. Nelson and J. E. Crawshaw.

"Correlation of Mechanical Loading with Haulage and Mining Systems," Howard N. Eavenson, chairman—(1) Review of Progress, D. J. Carroll; (2) "Determining Factors in Application of Various Types," Raymond A. Walter; (3) "Preparation of Mechanically Loaded Coal," Thomas F. Downing, Jr.; (4) "Mechanical Loaders for Rapid Entry Driving," Carl Scholz; (5) "In Connection with Room-and-Pillar Mining," David Ingle; (6) "In Connection with Longwall Mining," R. Dawson Hall; (7) "Relative to Mine-Car Haulage," James Elwood Jones; (8) "Relative to Conveyor Haulage," Everett Drennen.

"Recent Developments in Equipment for Preparation of Coal," Col. Warren R. Roberts, chairman.

New York Dealers Discuss Burning Topics

Presided over by Roderick Stephens, vice-president of the Stephens Fuel Co., the New York City group of the New York State Coal Merchants' Association held a meeting at the Hotel Pennsylvania March 25. Some of the subjects discussed were the economical use of anthracite, new standards in the preparation of anthracite, and coal vs. oil, the latter by George Cushing.

At the banquet, in the evening, Michael Burns was toastmaster, and the speakers were Senator Harrison, of Mississippi, whose subject was "Freedom in Business," and Mgr. John L. Delford, on "Timely Topics."

Conversion of Coal Consumers to Storage Idea Proves Only Temporary

Backsliding Now in Evidence Indicates Off-Season Buying of Last Year Was Dictated by Circumstances Rather Than Vision—Early Slump in Purchasing Presages Trouble for Railroads

By PAUL WOOTON

Washington Correspondent of *Coal Age*

Immediately on learning that the Jacksonville agreement had been signed, coal consumers apparently began to use their stocks. The production statistics and other information reaching the federal agencies concerned with coal indicate that the policy generally being followed is to curtail coal purchases or new commitments to make as large use as possible of these reserves.

Officials who are watching the trend in the coal trade are fearful that consumers are backsliding, if any of them were really converted to the storage idea last year. The real belief is that it was circumstances rather than vision and altruism that resulted in the large storage of last year, making possible the remarkable performance of the railroads during that year.

It is apparent that should the present trend go on unaltered, the railroads will be called upon next autumn to handle a high peak of coal movement at a time when they will be less able than ever before to handle such a contingency.

In 1923 coal consumers regularized their purchases of coal so as to make more uniform than ever before the employment at mines and the traffic burden on the railroads.

The characteristic curve showing coal production starts from a high point in January and drops gradually until May, when it turns downward sharply and runs at a low level until October, when it rushes again into the winter peak. In 1923, however, the curve was unprecedentedly flat. The curve of no other commodity was so free of peaks and valleys. The railroads were delighted. It made possible their premier traffic performance. The only coal that they had to handle during the crop-moving period was the normal production of 10,000,000 tons a week.

Even Movement Forced in 1923

In 1923 there was an unusual combination of circumstances, however, which did much to force the even movement of coal throughout the year. At the beginning of the year stocks were abnormally low because of the preceding year's strike. They were below the safety point. Consumers were well aware of it. They started to build up their stocks with a vim, because of the various uncertainties of the situation ahead. They even bought steadily on a declining market. This is an extraordinary occurrence in any commodity and doubly so when the commodity is coal.

Then just at the psychological moment the Interstate Commerce Commission handed down a decision which abolished assigned cars. It was virtual notice to the railroads that they must protect themselves in the matter of coal supply. They lost no time in

establishing reserves. They accumulated an amount of storage which had been exceeded only in one previous year.

The advent of 1924, however, found the situation reversed. Instead of low stocks, consumers were starting the year with very heavy stocks. Their stocks were above any margin of safety which has been regarded as necessary. The possibility of a strike, however, kept most consumers from drawing on their reserves. As a consequence production continued at a high rate until the Jacksonville agreement was signed. Immediately thereafter shipments began to decline.

The natural time to begin drawing somewhat on the stockpile is at the end of cold weather. This year, despite the continuance of cold weather, the curve has plunged downward far earlier than in the normal pre-war year. It has carried with it the spot price, which is now lower than at any time during 1923. The assumption is that it is going to be very difficult, indeed, to prevent a return to the old policy of living from hand to mouth.

Railroads Can Help Themselves

An unusual opportunity is offered by this situation for the railroads to help themselves and to do a public service. The carriers know better than does anyone else that they cannot handle the bituminous-coal traffic during a year of average prosperity if it cannot be spread fairly evenly over the twelve months of the year. The railroads use 28 per cent of the total bituminous-coal output. If they will concentrate their orders during the spring and early summer and build up as much storage as can be carried reasonably, they can do much to prevent a car shortage next autumn. In that connection the suggestion is advanced that an accounting system should be devised by the railroads whereby the use of cars for company fuel during periods of car shortage should be charged at the rate which the car would have been earning had it not been withdrawn from the commercial haul for which it could have been utilized.

This simple expedient, it is believed, would do much to prevent coal purchasing agents from speculating and withholding purchases for possible lower prices. At the same time it would give the railroads a figure in dollars and cents to bring home to them the losses of revenue which result from having to use large numbers of coal cars for company fuel during a period of car shortage when revenue freight is being denied movement.

It is possible that some plan will be worked out whereby inducements can be held out to consumers to store during the spring and summer months.

Hoover Denies Supporting Open-Price Associations

Commerce Secretary Hoover hit back hard when Samuel Untermyer attacked his proposal to Senator Capper that centralized buying should be legalized so as to meet the menace of foreign combinations in essential raw materials. Secretary Hoover meets the charges in a letter dated March 21 to Senator Capper, in part as follows:

"He knows or should know that his statement is absolutely false when he says I ever supported the so-called open-price associations. I informed him specifically and personally two years ago that he should not repeat this misstatement for it was false, and that I was vigorously opposed to this practice or any other form of price control. I have, in fact, repeatedly advised the business world that it should not be engaged in this practice regardless of whether it proved legal or illegal, because it was against public interest. Furthermore, as a result of the work of this department and the Federal Trade Commission most of these so-called open-price associations have been abandoned.

"He knows or should know that the Webb-Pomerene Act was passed under the last administration for the purpose of enabling American exporters, under regulation by the Federal Trade Commission, to establish joint selling agencies for foreign trade and that the act in express terms prohibits its use for the control of domestic prices or for any restraint of trade within the United States."

Move to Broaden Activities Of Bureau of Mines

Representative Robsion, of Kentucky, chairman of the Committee on Mines and Mining of the House of Representatives, has taken an unusual step in calling upon his committee to consider the broad proposition of how the Bureau of Mines can be made more serviceable to the mining industry. While there will be scrutiny of the existing activities of the bureau to determine whether or not equivalent effort expended in other directions would be of greater practical value, the main purpose of the study will be to find out how the work of the bureau may be expanded to greatest advantage.

It will be recalled that President Coolidge has declared himself to be in favor of a greater Bureau of Mines rather than attempting to create a Department of Mines at this time. In view of that declaration of administration policy, Representative Robsion believes that his committee is in a position to be helpful in determining the lines along which the bureau's activities should be increased. He expresses the personal hope that there may be a decided augmentation of the bureau's work in connection with the safety problem in coal and metal mines.

As this is written, the exact date for the conduct of these hearings has not been determined, but Chairman Robsion hopes to convene them early in April.

A New Kansas Row

The newest row affecting coal down in Kansas is the effort of Governor Jonathan I. Davis to replace James Sherwood, chief mine inspector, with Leon Besson, who was state inspector up to 1913, elected by the miners in the days of the old Society of Miners. The Governor announced the appointment several days ago. But he reckoned not with the Kansas Industrial Court, which declared, March 21, that its approval is necessary before the appointment can take effect, and that it may not approve. Besson is regarded as a radical and a friend of Alex Howat, deposed president of the Kansas district of the United Mine Workers. It is reported that Ernest Shaw, a deputy inspector, may get the appointment as a compromise between the Governor and the Court. Besson's appointment would be a Howat victory.

Georges Creek Miners Accept 8 per Cent Wage Cut

Two hundred coal miners who went on strike March 18 at the Jackson mine of the Georges Creek Coal Mining Co. at Lonaconing, Md., because of a reduction in wages, returned to work on March 20, after a conference with General Superintendent Gerdetz and a general meeting held on March 19. There was extended discussion of the proposed reduction, at the conclusion of which the miners in a secret ballot decided to accept the cut, and returned to work.

Notice of the proposed reduction was posted at the mine on Saturday, March 15. This company, in which Pittsburgh people are largely interested, continued to operate its mine in agreement with the union during the period following the 1922 strike when other mines were operating on a non-union basis, and paid miners the scale fixed by the union, being the only company of any size in the western Maryland field which did so. It was necessary not long ago to effect a reduction, so that the one just announced is the second. It is stated that the second cut contemplates a shift from day wages to the checking system of 85c. a ton. Production has been at the rate of from 10 to 15 cars of coal a day.

The only exception made to the general plan proposed by the company is as to the pay of miners employed in the longwall headings, who will receive a minimum of \$5 per day, eight hours to constitute a day, this eliminating the checking system of 85c. per ton. Otherwise there has been a general reduction.

It is stated by Superintendent Gerdetz that the proposed reduction averages about 8 per cent, applied to all classes of labor. He points out that prices have dropped nearly 30 per cent in the last three months and that the company cannot continue operations unless there is a reduction. He also states that the company has planned to increase its working force to 300 men.

May Evict Striker from Company House Without Notice, Says W. Va. Court

A "rule of property" decision that will establish a legal precedent for the mining industry everywhere in America was laid down in the decision of the West Virginia Supreme Court of Appeals at Charleston, W. Va., last week, in an appeal from an eviction suit.

Under this decision a mine owner may recover possession of his houses the moment his employees quit work, and without the slightest notice to them. He may use necessary physical force, such as knocking down doors or tearing out windows of the house, or may even tear down the house, if he chooses, while evicting a striking tenant who refuses to give up possession of a company house. This decision was handed down in the case of Watt Angel vs. Black Band Consolidated Coal Co., of Kanawha County, which was a test case in the state courts, on the part of the defendant company to obtain the "rule" which has been requested by federal courts when injunction cases are heard.

The syllabus in the case was written by Judge James A. Meredith, president of the court. The decision stated:

The houses are not kept for rent generally, but are occupied only by the company's employees, and then only by its consent. Under these conditions a miner is employed, is furnished a house, he moves in, continues his employment for a number of years, and the deductions for rent are regularly made from his wages every two weeks; he then voluntarily quits work and pays no rent thereafter. There being no agreement that he should occupy the house for any definite period, when he ceased work for the company his right to occupy the house also ceased.

Must Pay for Coal Mined in Federal Land in Alabama

Millions of tons of coal have been mined by individuals from government reserves in northern Alabama, according to federal investigators. G. B. Morgan and J. A. Ramsey, of the Government Land Office, after checking all available records in Montgomery and Birmingham, are now in Jasper, Ala., winding up the inquiry.

The inquiry covered 75,000 acres, and the investigators reported infringements on some of the most valuable coal lands in the state. It was announced that all the alleged trespassers will be given opportunity to settle amicably by paying the government for the coal taken. Otherwise suits will be instituted, it was stated.

The object of the investigation, according to Morgan and Ramsey, is not only to stop trespassing and collect damages due the government but also to take steps to insure protection of government reserves in the future. The government in years past has transferred many acres to the state government, but has always reserved mineral rights. The inquiry chiefly concerns this land.

More Illinois Mines Sold

Two more sales of Illinois coal property were completed last week. The Harrisburg Colliery Co.'s Harco mine was bought by C. E. Karstrom, representing other interests, and the two Newsam Brothers mines in the Peoria field were purchased by the Crescent Coal Co., of Peoria. The Harco mine, a 4,000-tonner and one of the leaders in Saline County, has been eyed with interest for many months by various Saline County interests, including Big Creek Coals, Inc. The titular purchaser, Mr. Karstrom, vice-president of the Shoal Creek Coal Co., was vice-president of Big Creek Coals until 1920. The purchase and operation of this mine by Mr. Karstrom does not change the name of the Harrisburg Colliery Co. and is not regarded as interfering seriously with a probable consolidation of the principal Saline County companies several months hence.

U. S. Steel Coal Output Jumps 42 per Cent

Coal mined by the United States Steel Corporation during the year ended Dec. 31, 1923, totaled 35,289,901 tons, an increase of 11,996,430 tons over the production in the previous year. Of the coal mined, 28,234,030 tons was used in the manufacture of coke and 7,055,871 tons was used for steam, gas and all other purposes. During the same twelve months 18,837,631 tons of coke was manufactured, of which 11,694,730 tons was produced by byproduct ovens and 7,142,901 tons was manufactured in beehive ovens.

During the year \$12,749,606.03 was expended in maintenance and replacements on the coal and coke properties, as compared with \$8,084,895.73 in 1922, an increase of \$4,664,710.30.

Capital expenditure on the coal and coke properties during the year were \$8,079,269, of which \$461,958.84 was expended for the acquisition of 2,073 acres coal lands in Fayette, Mercer and Greene Counties, Pennsylvania, and in Vermilion County, Illinois, and for 339 acres surface land in Fayette County, Pennsylvania. In the Connellsville district for facilities to increase the output of coal and for underground transportation \$3,688,250.26 was spent.

The corporation employs 33,354 persons on its coal and coke properties, as compared with 26,856 persons in 1922.

In the western Pennsylvania fields \$4,989,776 was expended in the opening and development of new coal operations.

The corporation spent \$1,763,417 during 1923 for accident prevention and safety work, as compared with \$1,175,171 in 1922.

The northern coal and coke property of the corporation comprises 252,908 acres of coking coal and 183,756 acres of steam and gas coals. The southern coal and coke properties consist of 171,617 acres of coking coal and 170,398 acres of steam and gas coals.

New England Dealers Assail
Badly Prepared Anthracite

The New England Coal Dealers Association held its annual convention in Boston on March 20 and 21 with a record attendance. Horticultural Hall was converted into something like a modern coal yard for the two days, and many of the latest appliances for handling coal were installed for exhibition purposes. Mechanical devices for scooping, loading and unloading were shown by the manufacturers, connected with electric power in the hall or operated by their own motors. The two leading coke producers of New England occupied large areas and there also was an exhibit of bituminous coal that had been chemically treated for domestic use. There were numerous belt loaders on exhibition, and dump wagons, coal trucks of many kinds, and a new type of bucket loader made up the rest of the equipment that was of special interest to the visiting coal men.

W. A. Clark, of Northampton, Mass., was elected president for the 12th year, and G. A. Sheldon, of Greenfield, Mass., and C. R. Elder, of New Britain, Conn., were respectively re-elected treasurer and secretary. Those elected vice-presidents were J. Calvin Miller (Maine), H. A. Osgood (New Hampshire), N. E. Pierce (Vermont), E. A. Wilson (Massachusetts), G. L. Miner (Rhode Island), and J. B. Gregory, Jr., (Connecticut). R. S. Hays, of Newport, R. I., and Herbert C. Edwards of Lewiston, Me., were elected to vacancies on the executive committee.

The feature meeting was on Friday afternoon, when a vigorous resolution was adopted conveying the dealers' "most urgent request to the anthracite producers that a more uniform and satisfactory standard be established and maintained." The preamble to the resolution declared that "the complaints of the public during the post-war years have convinced us that there must be abnormal impurities in anthracite," and "though we know that properly prepared anthracite is the most economical of fuels, the public will purchase any substitute for poor anthracite at present prices."

The convention then tabled another resolution in favor of limiting anthracite to two sizes, acclaiming the statement of a member of the resolutions committee that "the condition of the coal business is badly enough upset now, due to the bad quality of coal, without upsetting it more by changing the sizes."

There were two interesting addresses the same afternoon; one by Walter D. Rogers, executive secretary of the National Retail Coal Merchants Association, on "The Retail Coal Dealer at Washington," and the other by J. M. Dunphy on "The Small Anthracite Coal Problem and Its Solution," with special reference to the pyramid grate.

E. S. Brooks Dies at 66

E. S. Brooks, vice-president and general manager of the Union Pacific Coal Co., died at his home in Rock Springs, Wyo., March 17 of heart trouble at the age of 66. He became

Utah Miners Not Afraid

There is no superstition among Utah miners to make them hesitant about working in the burned-out No. 2 mine of the Utah Fuel Co., at Castlegate, in which 173 men were killed March 8. Possibly it is because many Utah miners want a chance to earn a living. Possibly it is because they want to work for a good company. But for whatever reason, more than 200 men outside the company's employ have already applied for jobs to replace the 173 dead men, and more applications are coming in.

superintendent of the company's mines at Hanna, Wyo., in 1894. In 1906 he was made superintendent of the anthracite mines of the Southern Pacific Ry. Co. in old Mexico and in 1911 took charge of the Washington Union Coal Co.'s Tono Mine, in Washington. Since 1920 he had been at Rock Springs in charge of the Union Pacific mines.

World Coal Output in 1923
Near High Mark of 1913

World's total production of all coal in 1923 was approximately 1,335,000,000 metric tons, according to the Geological Survey, but information is still incomplete. In comparison with the preceding year this was an increase of 112,000,000 tons, and it was but 7,000,000 less than the output in 1913, when the high record was established. The principal factor in the improvement over 1922 was an increase of 34 per cent in the production of all coal in the United States. All countries listed, however, with the exceptions of Germany and Japan, showed increases and the output by France was but 3,000,000 tons below the pre-war level. The

E. J. McQuail Ends Life

E. J. McQuail, chief executive of the Turkey Gap Coal & Coke Co., the Coe Pocahontas Coal Co., Ennis Coal Co. and American Coal Co., residing at Bluefield, W. Va., committed suicide March 24 by blowing out his brains with a pistol. No reason can be assigned for the deed. Those who were with him shortly before the act state that he was in his usual frame of mind and noted nothing out of the way.

Mr. McQuail was the son of William McQuail, who came to West Virginia from Shamokin, Pa., thirty-five years ago and opened up the mines of the Turkey Gap Coal & Coke Co. at Ennis. Upon the retirement of his father from active business about five years ago Mr. McQuail became the executive head of all the McQuail interests. He was about forty-five years of age, enjoyed good health, happy family relations and his coal companies are considered among the soundest of any in the state. James A. McQuail, of Mercer County, West Virginia, and Ennis McQuail, of Philadelphia, are brothers of the deceased.

world's output in 1923 was 16,000,000 tons larger than in 1920, an increase that was largely due to recovery in the production of the United Kingdom, France, Poland and Russia, which more than offset the decrease in the United States.

It is of interest to note the tremendous decline in the production of coal in Germany. According to a report by the German Imperial Coal Council, published in the *Colliery Guardian* of Feb. 1, 1924, the output of coal was 55,000,000 tons, a decrease of 58 per cent from production in 1922. The production of lignite also declined and totaled approximately 125,000,000 tons, a decrease of nearly 10 per cent. The report attributes the decline to the economic disorders that attended the occupation of the Ruhr.

Coal Produced in Principal Countries of the World in Calendar Years 1921, 1922 and 1923

(c) Exclusive of lignite from Japan (annual production of about 200,000 tons) for which estimate is included in total. (d) Estimated from figures for first 11 months.

Practical Pointers For Electrical And Mechanical Men

Where Electric Power Can Be Saved

Insulation Leakage, Poor Bonding, Use of Heaters and Lights Unnecessarily, Insufficient Cross-Section in Conductors, Underloading of Induction Motors All Cause Excessive Power Bills

IN the past when nearly all coal companies generated, at their own plants, the power used to operate their mines, employees were uneconomical in the use of electrical energy. They wasted it both in the mines and in their homes as if it were of no value. But now that the use of purchased power is increasing, we begin to realize our wastefulness and we are commencing to comprehend that something must be done to eliminate this costly and unnecessary expense.

On visiting mines, any number of wasteful practices may be noted, but one cause of loss that should be given due consideration on all such occasions is lack of electrical insulation. Some mines have smooth dry stone roofs, while in others the roof is damp and irregular, and in this a better quality of insulation is required if the current is to be used with economy equal to that attained with a dry roof.

INCOMPLETELY GLAZED INSULATORS

For an example, let us take the feeder circuit or "machine line" as it is commonly termed. This is usually arranged so that it may be cut in or out of service independent of the trolley circuit. It is probable that the most popular type of insulator now being used on this circuit is that known as the security insulator, which gives satisfactory service where little or no dampness is encountered. However, as its entire surface is not glazed, a path for the leakage of current is afforded if the insulator is exposed to excessive moisture for a considerable length of time. This leakage may be small, but when we consider the number of insulators employed under these and similar conditions, we shall soon realize that the total leakage or waste of current may form an important part of the monthly power bill.

Until some manufacturer of such products places on the market a wet-ware porcelain insulator for this particular purpose, I am unable to recommend any standard for use in such mines. However, I am firmly of the belief that the additional cost of a wet-ware porcelain product over the present grade of insulator would be small as compared to the savings that a reduction in the leakage of current would effect.

Other power losses from the electrical system are due to poor bonding, to

heaters operated needlessly, to lights kept burning when their illumination is not required, and to copper conductors of insufficient carrying capacity. Poor bonding is no longer excusable, especially since the new copper-weld bond has made its appearance on the market. These bonds are inexpensive, and little skill and labor is required for their installation. When properly installed they afford 100-per cent contact surface, this being an entirely new feature with welded bonds, especially when installed by an inexperienced operator.

A large saving of power may be effected by connecting all the lights and heaters to the trolley circuit, leaving none of them energized from the machine circuit where they would probably be left in operation every hour of the day and night, regardless of the requirements. When the last motor trip for the day is completed, the trolley circuit should be disconnected from its source of power supply, thus relieving the light and heater load. At the same time, the pumps, fans, necessary signals, etc., may be supplied with current from the machine circuit.

These minor electrical loads are seldom given any consideration by the employees of a mine, and frequently the executives in direct charge of affairs scoff at them. Nevertheless, such continued savings, though small, are sure to net a handsome reward.

LOST OVER 100,000 KW.-HR. A YEAR

As an example of the importance of such leakage, I am taking a rather modernly equipped mine with which I am familiar, which has an average output of approximately 1,200 tons per working day.

Through various tests at this mine it was shown that it was convenient to relieve the load of the trolley circuit about 8 hours of each working day, and the whole 24 hours on Sunday, or a total of 72 hours per week, which amounts to 3,744 hours per calendar year, without considering idle days. The waste load, due to leakage, lights and heaters was found to be 112 amperes, which at a pressure of 275 volts is approximately 31 kw., or 41 hp.; this in the 3,744 idle hours of the year would result in a loss of 116,064 kw.-hr.

Let us trust that the readers of this article will bear in mind the value of these large figures, and that in the

future on no occasion will they hesitate to take a few extra steps to prevent the use of any circuit unnecessarily.

Another consideration particularly pertaining to purchased energy is that of the power-factor. When induction motors are used it should be remembered that an under-loaded induction motor requires nearly as much current as when operated at full load; hence such motors should be applied to loads so as to operate at full capacity most of the time.

The loss of a credit for good power-factor or the payment of penalty for a poor power-factor may not seem to be large on a monthly power bill, but in the total power cost for the year, it may amount to a considerable figure. Many people forget that poor power-factor loads reduce the efficiency of the whole power system, resulting in a much greater consumption of power than necessary.

Checking Locomotive Wheels Before Using

Never be indifferent in regard to the condition of your locomotive wheels. They are just as important as any other part of the machine. Unless the wheels of a locomotive are of proper size parts of the locomotive frame, gear cases or the motors may drag on the ground with serious consequences. If the wheels have false flanges the track is soon torn to pieces, frogs and cross-overs are damaged and wrecks occur. Wheels which are not set at proper gage may spread the rails or become uncontrollable at switches.

These are only a few of the many reasons why locomotive wheels should be always kept in good operating condition. Even under normal operation the wheels of some locomotives may wear rapidly and must therefore be renewed. When it becomes necessary to change a set of locomotive wheels a thorough inspection of the new wheels should be made. Such an inspection should reveal any defects in the material, incorrect assemblage or design. If the tread of the wheels has not been properly shaped it may cause accidents as serious as those resulting from the use of wheels with false flanges. The wheel gage should be checked at the four quarters of the wheels so as to be sure that the axle is true and that the wheels and tires have been properly placed.

Necessarily the expense of renewing a set of locomotive wheels is always

Are Your Wheels True? With Gages Like This, You Can Find Out

Two saw-steel templates on the end of the gage are shaped to fit the standard wheel tread. By placing them on the treads the position of the wheels on the axle can be readily checked. Thorough inspection and the use of a gage like this will materially reduce accidents and delays.

great, for the locomotive must be taken out of service and large quantities of material must be handled and used at the expenditure of much labor. Consequently, the work should be well done and the material should be accurately designed. Ordinarily the work at the mines merely consists of changing the wheels and axles; that is, the machine work of assembling the wheels on the axles and the work of turning down worn wheel treads is done at a machine shop located some distance from the mine.

In any event, whether the machine work is done in the mine repair shop, located on the immediate property, or whether it is done at some outside shop, there is a great probability that the wheels may be out of true when they reach the locomotive pit.

To enable our electricians to check a new set of wheels before they are placed under a locomotive our depart-

ment designed a gage to be used for this purpose. This gage is made of two pieces of 1/8-in. saw steel cut to fit the shape of our standard wheel tread, and mounted on a piece of angle iron in such a position as to fit accurately a standard set of wheels when properly placed on the axle.

When a new set of wheels and axles are received at the mine a thorough check is made of the material and the gage is placed on the wheels at four quarter positions on the circumference. The templates at the ends of the gage show whether the treads are properly shaped. By this test it is possible to determine whether or not the material has been received in good condition. Later a similar test is made inside the mines to be sure that the wheels have not been damaged or the axle bent in transit to the locomotive pit.

Giving Trolley Bushings Lubrication and Life

In several articles that have appeared in *Coal Age* regarding trolley wheels and bushings, they have been truthfully described as the weakest parts in the equipment of an electric locomotive. It is easy to see why this is so. The 4-in. trolley wheel attains a high velocity when the locomotive is running at normal speed and the contact of the wheel on the wire is so small that it is a wonder that we get the good service that we do.

No electrician would think of connecting a 100-hp. stationary motor to a power line simply by throwing a wire or a cable over it. Yet such a wire would afford a connection almost as efficient as that which a locomotive has with the trolley wire by which it is energized, and few haulage locomotives are equipped with motors having a total capacity less than 100 hp.

The connection between a trolley wheel and trolley wire is poor even under the best of conditions, such as are found immediately after a new bushing and axle-pin have been installed. As the bushing wears and the axle-pin becomes pitted and roughened, the contact becomes bad. Springs are

often neglected, with the result that the wheel has much lost motion between its sides and the trolley harp. Of course, these conditions may be caused by the motorman not taking proper care of his trolley equipment. But you can find them in almost any mine, and this seems to indicate that something should be done to improve the performance of trolley wheels.

However, not all is said when it is stated that the contact is defective. It is expensive to be replacing bushings and axles constantly, and still more expensive to be discarding wheels before they are worn out, just because someone neglected to put in a new bushing. When the whole trouble is traced down, it seems to be a question of proper lubrication. Most motormen oil their wheels several times a day, but they pour the engine oil only on the outside, and in consequence it never gets to the center of the wheel where it is most needed. When a bushing is new it is too tight for the oil to penetrate very far, and if the bushing is old and worn, the thin layer of oil that clings to the surface does not last very long.

Not long ago, we decided to use a larger trolley wheel with a 3-in. axle instead of the 4-in. wheel we had been

using. When we received the new wheels and harps, I noticed the axle pins were made of ordinary 3-in. pipe with a small hole in each end for cotter pins. This hollow axle gave me an idea. I plugged one end of it and bored a small hole at the center of the axle and tapped the other end so that it would take a 3-in. high-pressure grease gun fitting similar to those used on automobiles. I also bored a hole at the center of the wheel bushing and marked its position on the wheel so that it could be aligned with the hole in the axle. With this arrangement, it is possible to fill the grease reservoir in the wheel through the hollow axle. When the wheel is in operation the grease will be forced out of the reservoir and lubricate the bushing and axle. A light grade of grease was used in the reservoir so that it would flow as required. The motorman filled the reservoir in the morning and gave his trolley wheel no more thought for the rest of the day.

The first trolley-pole head fitted in this way was still working without any appreciable wear on the bushing or axle after three trolley wheels had been worn out. There is no reason why one bushing should not outwear a dozen trolley wheels. We now make our own axles from solid steel, using a 3-in. elbow fitting instead of the straight one, thus making application of grease easier and avoiding a few minor defects that developed in the first axle.

Cleaning Insulation From Copper Coils

It has been common practice to burn the insulation from old coils. This should not be done where the coils are to be reinsulated and used again. The question then comes: How are we going to remove the old insulation? One big operator places the coils in an oven and passes steam through the coils for 12 or 14 hours. He finds that the insulation peels off easily while hot. Another operator dips the coils in a weak solution of muriatic acid for a time (approximately 24 hours), so that the acid weakens the insulation, but not long enough to give the acid a chance to eat into the copper. The necessary time required can easily be established by checking carefully and removing the coil when the brightening of the copper commences. After the acid treatment the coils should be thoroughly washed in clear water.

Production And the Market

Parting Blast of Winter Gives Brief Stimulus To Soft-Coal Markets; Prices Still Slipping

A blast of honest-to-goodness winter weather in a large section of the Middle West during the last week served to instill some sadly needed vim into the coal business. The improvement was not very broad in character, however, being confined mostly to domestic business, where consumers have been buying from hand to mouth for some time. Large consumers continue to place dependence to a large extent upon stockpiles, confident that they have nothing to lose—perhaps something to gain—by waiting to see what April 1 will bring forth. Continued price adjustments seem to justify the policy.

Another cloud in the industrial sky will soon be cleared away, an agreement being near between the Northern West Virginia Coal Operators' Association and the union mine workers after a conference at Baltimore lasting ten days. Wyoming also has signed up. Union representatives of the central Pennsylvania field wound up their meeting at Altoona last week with the adoption of a recommendation to seek the best scale obtainable for three years at a conference with the operators in Philadelphia this week.

Coal Age Index declined 3 points to 176, as of March 24, the corresponding average price being \$2.13. This compares with \$2.16 on March 17.

Raw Weather Awakens Midwest Markets

Domestic coal has been moving rather freely in small lots from Illinois and Indiana fields as a result of a parting blast of winter. Steam coals have their own troubles, however. The closing of a number of mines that is expected April 1 probably will have the effect of bolstering up this market somewhat. Mines in the Duquoin, Jackson County, Mt. Olive and Standard fields are working from two to four days a week and some of the mines are preparing for a long suspension.

In western Kentucky the mines are running only about a day and a half a week. Prepared sizes are moving better than expected, but in spite of an effort to hold prices firm, operators have been forced to accept the low side of the market range. Even with the light production of screenings in eastern Kentucky selling has been at low prices, the range being 75c. @ \$1.15. With a low market reigning there is a hope that there may be some early buying by lake shippers to load vessels at lower lake docks for early movement, though the normal start of the lake shipping is still rather remote.

Northwestern Markets Lifeless

Coal markets in the Northwest are absolutely without life, business being conspicuous by its absence. With about 1,300,000 tons of coal on the docks and demand lacking, prices have taken a tumble. Kentucky coal alone holds its level—because of the short supply. The Southwest is doing better, as a suspension is looked for, there being insufficient time to reach an agreement on wages between March 28, when the parley begins, and April 1.

A deadly dullness has settled over the Ohio markets. Similar conditions prevail in the Pittsburgh district and New England, and the situation in the Atlantic seaboard markets is little better. The Birmingham market is more optimistic, an improvement in inquiry and bookings having been noted.

Production of bituminous coal during the week ended March 15 amounted to 9,640,000 tons, according to the report of the U. S. Geological Survey, which was 23,000 tons more than was produced in the previous week. Output of anthracite totaled 1,941,000 tons, a gain of 59,000 tons compared with the previous week, when 1,882,000 tons was produced.

Midwest Domestic Coals Move

A burst of raw, wintry weather throughout the Middle West during the past week has moved a good deal of domestic coal from almost all Illinois and Indiana fields. This has enabled producers to maintain the new reduced circular on southern Illinois coals fairly well although there has been a good deal of selling of \$3 lump at \$2.75 in spite of the awakening of the market. All purchases have been in small lots, of course. The reduction of March 13 on Franklin County coals won back a good deal of dealer trade that has long been lost to cheaper coals. Downward adjustments in all other competing fields were made then or since.

Steam coals are in trouble, however. Southern Illinois moves with difficulty at \$1.90. A good deal is sold at \$1.75. Central Illinois is back to \$1.50@1.60 in spite of its short rate advantage to Chicago market. Indiana screenings are in a slight slump also. This is not expected to continue more than a few days because everybody feels the domestic business cannot run strong very long. A reasonable volume of it may be expected right through April, but probably the number of mines that will shut down April 1 will reduce the total production to a point that will bolster up the steam market.

Continued cold weather keeps domestic tonnage fairly active, principally on lump, with egg and nut moving slowly. The mines seem to have a pretty fair surplus of all sizes generally left over, however, and are getting from two to four days a week. Railroad tonnage is easing up and the car supply is plentiful and transportation good. Independents are having a hard time cutting prices on the association members, but they are temporarily getting away with it, although prices are below cost of production.

Illinois Mines Prepare to Suspend

In the Duquoin and Jackson County fields miners are getting about three days a week—those that are working—while several are idle. Throughout both of these fields mines are beginning to prepare for a long period of suspension. In the Mt. Olive district everything has slowed up, though there is a better demand for steam than the supply. Mt. Olive proper is asking \$3 for 2½- and 3-in. lump, while in the surrounding territory the price is \$2.75 for 6-in. lump. In the Standard field the future looks bad and prices now are cut to the bone. Mines continue to suspend operations and those that are working on commercial coal are getting two and three days a week with a hard time to find a market.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	March 24	March 17	March 10	March 26
Index	176	179	181	246
Weighted average price...	\$2.13	\$2.16	\$2.18	\$2.98

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

St. Louis Market Fairly Active

Continued cold weather with flurries of snow has kept the St. Louis domestic market fairly active for small orders and cheaper grades principally. Dealers are able to keep their yards cleaned up and a little coal continues to move regularly. Country domestic shows up fairly well on the cheaper grades. There is no demand for anthracite or smokeless, though there is a little activity in coke. Local wagonload steam is easing up and country steam is fairly active. Effective the 15th new retail prices were: Carterville, \$7.25@7.50; Mt. Olive, \$6.50; Standard, \$5.75; smokeless, \$14.50; anthracite grate and egg, \$15.75; anthracite stove and chestnut, \$16; byproduct coke, \$11; gas-house coke, \$10.50.

Kentucky Has Hard Sledding

Things are generally quiet in the Louisville market. It is reported that big buyers in many instances bought heavily in January and February, in the belief that there might be a general coal strike, and have been using up supplies on hand, with the result that even light production of screenings in eastern Kentucky has been selling at low prices. The present screenings market in Eastern Kentucky is 75c.@\$1.15 for nut and slack, including fine gas-coal screenings.

In western Kentucky, where mines are running only about a day and a half, screenings are quoted at \$1.25@1.35 for pea and slack, due to small production along with the fact that consumers who use pea and slack in automatic stoker feeds have been taking supplies rather freely in a

belief that there may be a shutdown of part of the field, which would almost close up production of the small size.

Prepared sizes are moving in spurts, and have been better than anticipated, due to continued cold weather in March. Western Kentucky is trying to hold prices firm, but is forced to accept the low side of the market range which is around \$2.75 for best block, \$2.50 for lump, \$2.40 for egg, and \$1.75@2 for nut, with mine run at \$1.40@1.85, and some stripper mine run at less than that.

In eastern Kentucky block is quoted at \$2.75@3.25, but \$3 is about the top on sales, as lump is \$2.50@3, egg \$1.75@2.25; nut, \$1.50@2 and mine run, &1.40@1.90.

In view of the present low markets there may be some early buying on the part of Lake shippers to load vessels at dock at the lower end of the lakes for movement in the early shipping season, but lake business hardly gets started as a rule before late May or early June.

Northwest Market Dormant

It would be hard to conceive of anything deadlier than the bituminous market at Duluth at present. There is absolutely no business. Mild weather and uncertainty over the question of railroad rates, and resulting prices, has caused the buyer to hold off in hope of lower levels. As a result of the fact that approximately 1,300,000 tons of free bituminous is on the docks at present and that this amount is not needed now, prices have taken a tumble. Kentucky is the only coal that is holding its level, and this because of shortness of supply. Screenings are firm only because of short supply. The general reduction has been about 25c., prices being as follows: Kentucky lump, \$7, run of mine, \$6; screenings, \$4.25; Youghiogheny lump, \$6; run of mine, \$5; screenings, \$4.25; Hocking lump, \$5.75; run of mine, \$4.75; screenings, \$4; split lump, \$6.25; run of mine, \$5.25; screenings, \$4.25; Pocahontas lump, \$7.50; run of mine, \$6; screenings, \$4.75@5.

The coal market at Milwaukee is dormant, with little or no demand from city or country. There has been no change in the established schedule of prices on either hard or soft coal, but something is expected to happen by April 1. Mild weather continues to reduce coal consumption to the minimum.

West Does Better

A suspension of work for at least thirty days is expected in the Southwestern district as a result of the delay in the wage scale parley between operators and miners, which will begin in Kansas City March 28. It is considered unlikely that an agreement will be reached by April 1, when present contracts expire. In the meantime, as a result of continued cold weather and the recent reduction in price of domestic grades of Kansas coal, the market is absorbing the full output of the mines, which are working better than 60 per cent of normal time. Tracks are virtually clear of screenings, and only a few "no bills" of lump and nut are reported. Kansas coal is quoted at \$4.50 for lump; \$4 for nut; \$3.25@3.50 for mine run and \$2.50 for screenings.

The coal market in Colorado was considerably stimulated in the last week. Mines worked on an average of about four days in the southern fields. The present spell of seasonable weather has contributed much toward the coal industry and it is expected that business will be much better if this weather continues. Prices remain unchanged. The transportation and equipment situation has been very favorable throughout the state except in Routt County, where practically 90 per cent of the working time was lost on account of extremely bad weather preventing any railroad movements.

Steam coal is finding a better market in Salt Lake City now than domestic sizes, but the market is still characterized by dullness. Mines are working not more than two days a week, which is making it difficult for most of the operators to supply the demand for slack coal, now selling all the way from \$1 to \$1.50.

Sogginess Pervades Ohio Markets

In spite of reports that production has been edging off elsewhere and that here and there mines are closing down south of the river the record of car interchange at Cincinnati shows little diminution. Everything is up in the air. The market is soft and soggy. Domestic and run of mine prices got the worst of the slicing, so far as the price lists on high volatile is concerned. Producers of

standard Pocahontas and New River are standing by their guns and holding tight to the circular prices that came out March 1. Talk of contract business is being heard, though few are being entered into. Specialized coals are quoted as follows: Egg, \$2.50@\$3; block, \$3.50@\$3.75.

Dullness is the prevailing note in the Columbus market. Both the steam and domestic trade are quiet, not much business being booked. Retailers have fair stocks and with the winter practically over are loath to increase their stocks. Buying is from hand to mouth. Retail prices are irregular and there is considerable cutting among dealers in order to clean up before the stocking season. Utilities are using reserves largely. Railroad contracts are now being considered and they are going at extremely low figures. Several large railroad contracts were let during the past week. Steam prices are weak and irregular and there is a fair amount of distress coal on the market. Weakness in screenings has developed, but this is expected to be temporary.

There is little or no change in general market conditions at Cleveland. Operators and jobbers say that inquiries are mighty scarce; that there is little or no negotiation for contracts, and that there is still plenty of stock or surplus fuel in the coal piles of industries, public utilities and railroads. A taste of early spring weather during the past week has, if anything, depressed the retail market, and the yards still have good stocks from which present demands are being supplied. Inquiries from brokers for quotations on contract tonnage in large quantities are looked upon simply as feelers.

Production in the Pittsburgh district continues to decrease. The spot market is practically stagnant. Inquiry is limited and sales are hard to make. Some further wage reductions are being made in the Connellsville region, but at mines that ship steam coal.

The situation at Buffalo shows no change for the better. Complaints of poor business seem to increase, though they have been widespread for several months.

New England Dullness Unrelieved

In New England the market continues without relief from the dullness that has prevailed now for several months. In no direction are there signs of immediate improvement; both all-rail and by water there is a great dearth of business, and buyers are quite content to await developments. Among a few small consumers there is a certain amount of inquiry, but the larger steam users are well stocked for the present and there is no anxiety whatever over price or supply.

The Hampton Roads coals are holding reasonably well at what for most of the producers is the bare cost of mining. No. 1 Navy standard Pocahontas and New River can be had at \$4.60@\$4.75 per gross ton f.o.b. vessel at the Virginia terminals, but in some instances the agencies are withholding sales at this range and are sending prepared coals west, where the current market will yield a slightly more favorable return. Occasionally a sale offshore will net more than coastwise business, but there is no volume in that direction and there are few orders to pick from.

At Boston, Providence and Portland for inland delivery there are ample supplies available, and prices are none too strong. Those factors who are equipped with rehandling plants have a distinct advantage and quotations are held low enough to discourage others from sending coal forward on the market. On-car figures range from \$5.80 to \$6.25, but most of the current sales are at less than \$6.

Retail prices in Boston continue fairly weak, due to local

trade conditions. The published price is \$6.50 per net ton delivered, but the average figure paid by larger users is much less than that. About the only favorable aspect of this situation is the pause it is giving to the oil business.

Vim Vanishes from Seaboard Markets

Spot soft coals are moving slowly in the New York market. Consumers are not disposed to add to their reserves although prices are about at the lowest level possible. Stockpiles of many consumers are large enough to last for several weeks and the tendency appears to be to drive the market further downward. Most contracts expire in another week and many of them have not as yet been renewed, many consumers still clinging to the thought that there will be plenty of free coals at low prices. The daily average number of cars at the harbor terminals sticks close to 2,000, most of which is on contract.

While the Philadelphia market shows some signs of weakness, quotations have been fairly well maintained at about the same level as last week. Consumers are still working off a great deal of their stockpiles and will likely continue this practice for several months. Naturally this has checked current sales, and the producers are looking forward to the time when they will again buy in excess of current needs to build up the stockpiles for another season.

With the announcement, following the ten-day conference in Baltimore between the Northern West Virginia Coal Operators' Association and the United Mine Workers, that agreement had been reached on nearly all points in controversy, the last cloud in the industrial sky has almost disappeared. The new contract undoubtedly will be signed before March 31, when the old agreement expires. Meanwhile the market is in poor shape, with production large despite the fact that much of the coal is being produced at actual loss to operators, and wherein the demand is comparatively small.

Anthracite Bought Only as Needed

Notwithstanding the nearness of April 1, New York retail anthracite dealers are taking in all the company domestic sizes they can store. At the same time they are soliciting their trade for orders based on last winter's requirements, and in some cases are informing the customer that his quota is being reserved for him subject to his order, stating the time of delivery. Nothing is being said of prices. There is a subnormal demand from wholesalers. Consumption is no heavier and users are not buying more than is actually needed. Prices for independent coals are easy with many orders placed at below the maximum figure. Stove coal is the strongest in demand while many dealers are anxious to put in a supply of chestnut. The trade at Philadelphia has been fortunate that the weather all this month has been conducive to coal burning. The consumer continues to order meagerly. The Pennsylvania Retail Coal Merchants' Association suggests that mine prices be reduced 50c. a ton and the dealers reduce 50c., making \$1 in all for April, and then advanced 25c. a ton for two months, but the operators are silent and no intimation is to be had as to their decision.

Foreign Market And Export News

Strong Demand in British Coal Market; Production Advances

The Welsh market shows marked improvement. Shipments have been seriously delayed by the lack of tonnage, but this is now coming forward much more freely, and the docks are busy again. There is still much talk of a strike in April, though the union leaders are at much pains to emphasize that a strike is not necessarily the natural outcome of the termination of the wage agreement.

These circumstances tend to increase the demand for Welsh coal, and the operators are quoting firm prices.

Negotiations have been reopened for the purpose of obtaining resumption of the three-shift working system. All collieries are overbooked with orders until the middle of April, and the trade is reluctant to accept new business.

The Newcastle market is somewhat stronger due to pressing European demands in anticipation of a strike in April. Most of the collieries are well booked into early April. France is in the market for gas and coking coals. German demand is slow and Scandinavian inquiries are hampered by ice in the Baltic. The French State Railways are asking tenders for 100,000 tons of Durham coking coals for delivery over the next six months.

Production by British collieries during the week ended March 8 a cable to *Coal Age* states, was 5,742,000 tons, according to the official reports. This compares with 5,702,000 tons in the week ended March 1.

Hampton Roads Business Slumps; Storms Hamper Shipping

Business at Hampton Roads during the last week has been slower than for many weeks, prices taking a slump and consumers apparently using all their old contracts prior to the new contract period, beginning April 1. Fair dumping at the piers was mostly of coal sold on old orders.

Recent storms have had the effect of

tying up shipping to a great extent, and many vessels were long overdue for cargoes. The result was a piling up of approximately 7,500 cars of coal, with nearly 500,000 tons at Hampton Roads piers. Coastwise business is slack, and the bunker trade fair. Overseas shipments of spot coal were negligible.

The tone of the market is weak, with little hope for better business before April 1. Overproduction also is indicated in advices from operators to agents.

French Producers Balk at Wage Rise; Markets Active

Wage negotiations in the coal fields hold the center of interest in the French coal market now. The wage settlement arranged last November was to be effective until Feb. 29. Because of higher living costs the miners, at a recent meeting asked not only for the maintenance of the old wage, but for a further increase. Having just reduced their selling prices the companies refused to accede to the demand, but agreed to maintain the present rates to the end of June. Although the miners are not entirely satisfied with the terms, there was no threat of a strike, though there may be some trouble raised by extremists.

Demand for household coals continues to be rather active, but owing to a shortage of trucks, the collieries have to store their output. Inquiry for industrial coal is larger and the output sells freely, and the movement would be greater still if supplies were sufficient.

Production in the Ruhr is steadily increasing, and Allied reparations shipments in February were only a quarter of a million tons below the reparations program. A new organization has been formed to succeed the S. C. O. F. in distribution of reparations coal, but the extent of its functions has not yet been defined.

According to statistics for the last quarter of 1923, just given out, for all French mines, the production is 810 kilograms (about 1,782 lb.) per day per underground worker and 569 kilograms (about 1,242 lb.) for underground and surface. Before the war, the average daily production per day was 978 kilograms (about 2,156 lb.) per underground worker and 695 kilograms (about 1,529 lb.) for underground and surface.

Progress in the restoration of the devastated mines of the Nord and Pas-de-Calais is indicated by the fact that production of coal in January totaled 2,082,821 tons; coke, 140,663 tons and patent fuel, 156,875 tons, compared with December output of 1,834,015 tons of coal, 133,364 tons of coke and 147,864 tons of patent fuel.

Traffic News

Rates in Bash-B. & O. Case Not Unreasonable

Interstate Commerce Commission Examiner Carter has recommended to the commission that findings substantially as follows be submitted in the case of C. E. Bash & Co. vs. the Baltimore & Ohio R.R.:

"Rates on bituminous coal from Ohio and the inner and outer crescents to various Indiana points are found not unreasonable, unjustly discriminatory or unjustly prejudicial except as provided in the commission's orders in the Ohio-Michigan coal cases and the Indiana State Chamber of Commerce case.

"Rates on bituminous coal, carloads, from Ohio to Huntington, Ind., prior to March 1, 1922, are not unreasonable.

"Rates from West Virginia to Gary and Michigan City during the period from Aug. 26, 1920, to June 30, 1922, were not unreasonable.

"Rates from the inner and outer crescents and from Cincinnati to Ben Davis, Ind., have not been and are not unreasonable.

"Rates from Louisville & Nashville mines in Kentucky to Wabash, Ind., from June 11, 1920, to Sept. 14, 1921, were not unreasonable."

Central Indiana R.R. Now in Better Condition

Recall of an order for sale of the Central Indiana R.R., a coal line operating between the southern Indiana coal fields and Muncie, and which has been in the hands of a receiver, William P. Herold, of Indianapolis, for several months, was issued recently in federal court by Judge A. B. Anderson. The order was issued on petition of the Central Trust Co., of New York, trustee for the bondholders, in which it was set forth that the decree and judgment of the court in favor of the company had been complied with, and asking the return of the railroad property to the Central Indiana Corporation, with the exception of the cash and accounts of the receiver. The stock is held by the Big Four and Pennsylvania railroads, which, it is understood, will continue to operate the railroad.

Modifies Western Rate Findings In Wyoming-Colorado Traffic

The Interstate Commerce Commission has modified its findings in the Western coal-rate case in so far as it applies to interstate rates from Rock Springs-Kemmerer to certain points in Colorado. The commission points out that in view of the substitution of certain rates by the Wyoming commission and with these intrastate rates in effect, the rate relationships which were found proper at Cheyenne, where the coals meet, will be disturbed to the disadvantage of the Colorado operators unless a

modification is prescribed. "The rates which the Wyoming commission now has prescribed," says the commission's decision, "may be used for the purpose of fixing relationships with the interstate rates from the Colorado district."

Seek Lower Short-Haul Rates In West Virginia

Several chambers of commerce and industries in the northern part of West Virginia having asked an adjustment of rates on fuel from the mines to distances not to exceed ten miles, a hearing was held by the Public Service Commission of West Virginia about the middle of March. A general reduction of about 10 per cent is asked, the complainants contending that short-haul rates on fuel in West Virginia are higher than similar rates in Ohio and Pennsylvania. The Public Service Commission inquired as to the absence of traffic officials of the railroad companies and indicated that unless traffic officials appeared, the commission would be disposed to grant the request of the complainants.

Indiana Roads to Fight Rate Cut

Indiana railroads have decided to oppose the order of the Indiana Public Service Commission for a reduction, effective April 1, in freight rates on coal amounting to approximately 10c. a ton. The reduction, the roads contend, means an annual loss in revenue of about half a million dollars. It will be contested in the courts, the way to carry it to the courts having been paved when the Indiana commission refused the carriers a rehearing. On the refusal it is possible to file briefs in court against the cut, which was obtained through the Indiana Chamber of Commerce, Indiana coal operators and the United Mine Workers of Indiana.

Final Argument on Hard-Coal Rate From Buffalo to Twin Cities

Final argument on the rescinding of the joint rate on hard coal from Buffalo to the Twin Cities will be heard on March 28. The Twin City Coal Exchange will be represented by its attorney, S. B. Houck, of Minneapolis.

I. C. C. Suspends Cancellation Order

The Interstate Commerce Commission on March 19 suspended until July 18 certain schedules which proposed to cancel rates on bituminous coal from mines in Kentucky, Virginia and West Virginia moving via La Crosse, Ind., in connection with the Pere Marquette Ry. to certain destinations in Michigan and Wisconsin, which would result in the application of highest combination rates via the eliminated routes.

Industrial Notes

As the result of a recent survey the General Electric Co. has established service and repair shops at Atlanta, Chicago, Los Angeles, New York, Kansas City, Minneapolis, Oakland, Philadelphia, St. Louis and Seattle, in addition to such service maintained at the factories. Each of these shops has the personnel and facilities for any form of service work on machines up to 500 hp., some of the larger shops being equipped to handle apparatus of any size. These shops also are prepared to furnish competent men on short notice in case of accidents or for any emergency work.

The name of the business heretofore conducted as L. A. Green has been changed to the L. A. Green Railway Equipment Co., First National Bank Building, Pittsburgh, Pa. The policy, purpose, personnel and organization of the company remains unchanged. The company distributes rails, machinery and equipment for mills, mines and contractors and manufactures "Durabil" steel frogs, switches and crossings.

Obituary

Henry Kulp Stauffer, vice-president of the Pittsburgh Terminal Coal Co., of Pittsburgh, Pa., died March 12 at his home in that city, aged 51. Mr. Stauffer entered the coal business 31 years ago as a clerk in the employ of the Berwind-White Co., at Punxsutawney. Later he was associated in various capacities with the following companies: David E. Williams & Co., Allport Coal Co.; Flenner, Hendrickson & Stauffer, Watkins Coal Co., Lennox Coal Co., B. Nicoll & Co., and since last November as vice-president in charge of sales for the Pittsburgh Terminal Coal Co. He leaves a wife and two daughters and is also survived by his brother, J. C. Stauffer, of W. L. Irish & Co., and by his mother.

Coming Meetings

Association of Iron and Steel Electrical Engineers. Fuel Saving Conference, April 2 and 3, William Penn Hotel, Pittsburgh, Pa. Secretary, J. F. Kelly, Empire Bldg., Pittsburgh, Pa.

Canadian Retail Coal Association. Annual meeting, April 3 and 4, King Edward Hotel, Toronto, Ont., Can. Secretary, B. A. Caspell, Brantford, Can.

American Institute of Electrical Engineers. Spring convention, April 7-10, Birmingham, Ala. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

American Welding Society. Annual meeting, April 22-24, Engineering Societies Building, 33 West 39th St., New York City. Secretary, W. M. Kelly, 33 West 39th St., New York City.

National Exposition of Coal Mining Equipment and Machinery of the American Mining Congress, May 12-17, Cincinnati, in conjunction with the annual meeting of the National Coal Association.

National Coal Association. Annual meeting, May 14-16, Cincinnati, Ohio. Executive Secretary, H. L. Gandy, Southern Building, Washington, D. C.

International Railway Fuel Association. Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

The American Society of Mechanical Engineers. Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

The National Foreign Trade Convention. June 4-6, Boston, Mass. Secretary, O. K. Davis, 1 Hanover Square, New York City.

National Retail Coal Merchants' Association. Annual meeting, Hotel Virginian, Bluefield, W. Va., June 4-6. Secretary, Walter D. Rogers, Transportation Building, Washington, D. C.

American Society for Testing Materials. Annual meeting, Chalfonte Hotel, Atlantic City, N. J., June 23-27. Secretary, Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

News Items From Field and Trade

ALABAMA

Chickasaw Shipbuilding & Car Co., Fairfield, subsidiary of the steel corporation, has been awarded a contract for 1,800 freight cars by the Louisville & Nashville R.R. which is 47 per cent of a total of 3,900 cars which the railroad company has placed orders for. The Chickasaw order represents an expenditure of \$4,200,000. The Southern Ry. also has placed an order with the above company for 750 hopper cars.

Salmon & Cowin, mining engineers and contractors, Birmingham, have been incorporated with an initial capital stock of \$3,000, to do a general engineering business. Herbert S. Salmon is president; Percy C. Cowin, vice-president and treasurer.

The Wadsworth-Cahaba Coal Co., Inc., Birmingham, has increased its capital stock \$23,000.

ILLINOIS

The Operators' Association of the 5th and 9th Districts has decided to restrict its activities and expenses by discontinuing its statistical department. Paul H. Greenlaw, of St. Louis, Mo., who is in charge of statistics and has been associated with the organization for eight years, will sever his connection as soon as he winds up the department's affairs. During the Fuel Administration he was appointed assistant district representative by Dr. H. A. Garfield, U. S. Fuel Administrator, and Deputy Fuel Distributor by Wallace Crossley, Federal Fuel Administrator for Missouri. During the strike of 1919 he was appointed member of the Southwestern Regional Coal Committee by Dr. Garfield, and by this committee was chosen its chairman.

The Melike brothers, Rudolph, Fred and Herman, have bought Section 1 coal mine, located about three miles southeast of Coal Valley. It was formerly owned and operated by J. M. Pryce and son. The mine employs about twenty-five men. Mr. Pryce was formerly the operator of the Eureka mine, located one mile southwest of Coal Valley. This mine closed about two years.

Mine No. 2 of the **Mount Olive & Staunton Coal Co.,** near Williamson, produced 5,128 tons of coal March 4, which was a record for that mine and is said to be the record for Madison County. The mine is 317 ft. deep, the deepest in the county. This mine operated 212 days last year, more than any other mine in the county and produced 787,792 tons of coal, also the peak for Madison County. Normally, 700 men are employed.

Production of 400 tons of coal has now been reached by the **Shuler Coal Co.,** at its new mine at Alpha. Operation of the mine was begun last fall and production has steadily been increased. A considerable part of the output is sold in the Davenport-Rock Island-Moline district.

The Superior Coal Co., at its No. 1 mine, Gillespie, hoisted 3,001 tons of coal March 3, in eight hours. To accomplish this output 1,625 mine cars were hoisted at the rate of 203 pit cars per hour, which required a railroad train of 103 cars to convey from the mine.

On March 12 the **Kathleen mine,** at Dowell, brought up 5,286 tons, breaking its record again. The prior record was 5,262 tons.

INDIANA

Charles W. Whitlock, an attorney, was named receiver by Judge John P. Jeffries in Terre Haute, for the **Otter Creek Coal Co.,** following the filing of a suit by the Wolverine Coal & Mining Co., of Chicago, in Circuit Court, against the Otter Creek Co., asking for a receiver.

KANSAS

Five months back pay to Alex Howat, deposed president of District 14 of the union, was proposed at the March convention of the District. John L. Lewis, International president, checkmated this attempt to aid the disturber, Howat, by

warning the district that if it made such payment it would be prosecuted for misappropriation of union funds. The convention then directed the district board to appeal the matter to the International executive board.

KENTUCKY

The Merchants Ice & Cold Storage Co., Louisville, has placed a contract for **Harlan screenings** at \$1.50 a ton. A contract which had until June to run was cancelled as of March 15 giving the company the advantage of 15c. a ton over the period to June, when the old contract would have expired according to an official of the company. It is said that the contract went to the **Blue Diamond Coal Sales Co.,** Cincinnati, and that the former contract was at \$2.25, later scaled down to \$1.65.

MARYLAND

The J. D. Walker Coal Co. has purchased property in Caton Ave. near Frederick Ave. on the Pennsylvania R.R., Baltimore, for a coal yard that is to be one of the largest in the city. The company, which mines its own anthracite and bituminous coal, will specialize in a substitute for anthracite, which is intended especially for households.

MISSOURI

The Harmony Coal Co. of Kansas has been incorporated to do business in Missouri and will have headquarters in Foster. The company will mine coal and sell it at wholesale and retail. W. R. Schooley, of Foster, is the principal agent in Missouri.

The Central Coal & Coke Co., Kansas City, announces the appointment of G. L. Parsons as general sales manager and of F. H. Oliver as sales manager.

John Woodruff, a coal miner, has sued the **United Mine Workers** for \$30,000 damages for injuries he says he received three years ago when a crowd of union miners from Richmond visited a mine near Excelsior Springs where he worked and tried to convince non-union men they should join the union.

The Federal Trade Commission has issued a complaint against the **Boehmer Coal Co.,** of St. Louis, charging it unfairly represented its coal to be "Victory coal," causing the trade to confuse this with "Victory coal" produced by the **Victory Collieries Co.**

NEW YORK

Stockholders of the Consolidation Coal Co. have approved the issue of \$10,000,000 7 per cent cumulative preferred stock. It will be offered to stockholders of record March 29, at par on the basis of one share for each four shares of common.

Governor Smith on March 21 signed the McGinnies bill as chapter 55 of the laws of 1924, amending chapter 581 of the laws of 1923, entitled "An act making an appropriation for the preparation of plans and specifications by the State Engineer and Surveyor for the construction of tipples for coal at Ithaca and Watkins, with a view of facilitating the transportation and delivery of coal," by extending until Feb. 1, 1925, the time such report shall be filed and providing for an estimate of cost to accompany such report of needed equipment and facilities. A reappropriation of \$9,782.27 is made to carry out the provisions of the act.

The Consolidation Co. reports for the year ended Dec. 31, 1923, a net income of \$2,585,473, equal to \$6.43 a share on the \$40,205,448 capital stock outstanding, after deducting depreciation, interest, federal taxes, etc. This compares with a net income of \$2,558,445, or \$6.36 a share, on the same amount of capital stock outstanding as of Dec. 31, 1922. The surplus for the year amounted to \$173,403, as compared with \$146,411, making the profit and loss surplus \$5,485,735 against \$5,442,955 for 1922. As of Dec. 31, last, the current assets stood at \$21,824,164 and current liabilities \$18,810,843 leaving net working capital of \$3,013,321, as compared with \$15,827,416 at the close of 1922. During

the year the company advanced substantial funds to carry forward the development of its mines in the Pocahontas-New River Division, acquired in 1922, says President Watson. It also was found possible, he added, to re-enter foreign markets on a somewhat larger scale. The increased expenditures required for this expansion account for the principal increases in the floating indebtedness of the company, according to Mr. Watson. F. W. Wilshire, vice-president, has been elected to the board of directors to succeed Frank Anschul.

Arthur Lathrop Zerbey, formerly with W. A. Marshall & Co., has joined the **Fuel Service Co.,** 17 Battery Place, New York City, as vice-president.

NORTH CAROLINA

The first trainload of coal mined in North Carolina was hauled into Raleigh by the Norfolk-Southern R.R. The train consisted of 18 standard cars, each carrying 50 tons of coal. Ten cars of this coal came from the Cumock mine, in Lee County and eight from the new Carolina mine. The Norfolk-Southern has been using this regularly for many months and finds it satisfactory for railroad purposes. This shipment was the first of such magnitude to be hauled away from these North Carolina mines, but it promises to be the precursor of thousands of other shipments.

OHIO

"Getting the Most Out of Your Coal Fire" is the title of a booklet being distributed by the Columbus Coal & Lime Co., of Columbus. The booklet is not an advertisement for any particular brand of coal or any make of heating apparatus but to insure the coal users of getting the most heat from fuel. Methods of firing suggested for different coals are said to be the result of tests made by the author, L. R. Taylor, during his years as a heating engineer. In his introduction Mr. Taylor says: "Method of operation, although it may not be so recognized, is unquestionably the prime factor in determining fuel consumption and freedom from operating troubles, no matter what fuel is being used."

Suit for the recovery of \$84,000 was filed in the federal court at Columbus by the ten heirs of the late Lorenzo D. Lively, of Jackson, against the **Chapman Coal Co.,** of Columbus. The heirs of Lively, who died in 1901, claim that in 1919, 1920 and 1921 the Chapman Coal Co. wrongly forced underground entries into 30 acres of land of the Lively estate and removed 12,158 tons of coal, for which the above amount is sought. The plaintiffs in the action are widely scattered.

William O'Toole, former vice-president of the central Pocahontas Coal Co. and minister to Paraguay, arrived on the Str. "Southern Cross" at New York on March 17, for a furlough of three months in this country. A telegram to manager Heitzman at Cincinnati carried the information that he intended to visit former acquaintances in Cincinnati after a few weeks at Welsh and a visit to his father, General O'Toole at Gary, Va.

PENNSYLVANIA

By a unanimous vote of the stockholders the capital stock of the **Lehigh & Wilkes-Barre Coal Co.** has been increased from \$10,000,000 to \$30,000,000 divided into \$10,000,000 7 per cent preferred and \$20,000,000 in common stock. The increase, it was said, was to bring the authorized capital in line with the price paid for the purchase of the coal company's holdings from the Central Railroad of New Jersey. Officers were elected as follows: C. F. Huber, president; Douglas Bunting, vice-president and general manager; Daniel Anthony, vice-president and general agent; Charles E. Ash, secretary-treasurer and Jackson E. Reynolds, John L. Kemmerer, S. B. Thorne, George R. McLean, Gilbert S. McClintock and Douglas Bunting, directors.

There were 180 fatal accidents in the mines of Pennsylvania during the first two months of 1924, the number being unusually high because of the mine catastrophe in Indiana County on Jan. 26, when 37 lives were lost. In January, according to the records of the Bureau of Workmen's Compensation of the State Compensation Board, there were 39 fatalities in the anthracite mines and 65 in the bituminous mines. In February there were 46 deaths in the anthracite and 30 deaths in the bituminous mines. The total compensation paid or awarded, including \$550,146 awarded in fatal cases, amounted to \$751,974 in January, and \$784,811 in

February, including the sum of \$444,727 paid or awarded in fatal cases.

The partnership of Geo. E. Henry & Son, of East Brady, will be dissolved April 1 and its affairs terminated as promptly as possible. J. Wilson Henry is organizing the Henry Coal Mining Co., which will take over the business. None of the assets or liabilities of the partnership will be transferred to the new company which will stand on its own feet.

VIRGINIA

The City of Norfolk is asking for bids on 9,000 tons of steam coal, and the State of Virginia is asking for bids on 60,000 tons of steam coal. The Chesapeake & Ohio R.R. is in the market for 1,800,000 tons, and Norfolk agencies will submit bids in all cases.

WEST VIRGINIA

With a view to operating on a large scale the Big Otter Collieries Co. has been organized with a capitalization of \$300,000, the general offices of the company to be at Wheeling. Principally interested in the new coal corporation are J. E. McClay, Charleston; R. J. Cotts, R. B. Herndon, H. A. Crowther, of Wheeling, and C. E. Molloy, of Heaters.

The Philadelphia & Cleveland Coal Co. has begun excavations for its new coal-loading terminal on the Ohio River at Twenty-sixth Street, in Huntington—an improvement which will involve an expenditure of about \$150,000. At the new terminal the company will transfer coal coming from the mines in cars to barges and will ship to Addyston, Ohio, near Cincinnati, where the coal will again be loaded into cars and shipped to the Lakes or to inland Western markets. The company has already expended about \$250,000 on its plant at Addyston. In building a river loading tippie at Huntington the company is arranging to install from 1,800 to 2,000 ft. of track together with a concrete overhead crossing at Twenty-seventh street. After the coal has been dumped into a large concrete basin it will be conveyed through a trench-like arrangement on a broad rubber conveyor to the barges where there will be a fall of not more than 4 ft. It will require about six months to complete work on the Huntington river terminal.

The Banfi Coal Co., of Follansbee, has been organized with a capital stock of \$25,000, the general offices of the company to be at Follansbee. Actively interested in this company are Andrew M., Helen M. and John M. Banfi, all of Follansbee.

The Three States Coal Co. with general offices at Bluefield, at its annual meeting elected officers as follows: C. A. Clyborne, president; F. T. Beazley, vice-president; J. Coy Pearce, secretary; V. H. Campbell, treasurer. The treasurer of the company also will act as assistant to the president. He was until recently district manager of the W. E. Degans Coal Co., of New York.

The Sitnek Coal Mining Co. has elected the following directors: Louis Sitnek and R. L. Rankin, of Philadelphia; S. H. Harold, of Uniontown, Pa.; Edwin Cramp, of Fairmont, and Harvey H. Stagers, of Fairmont. The directors elected the following officers: Louis Sitnek, president and general manager; Edwin Cramp, general superintendent; R. L. Rankin, secretary and treasurer; H. H. Stagers, assistant secretary. The Sitnek company recently purchased the Katherine mine of the Antler Coal Co. at Lumberport, and is making extensive improvements, including the installation of mechanical loading machines. These machines are said to be the first to be tried out in the Pittsburgh seam in northern West Virginia. According to general report, the company will extend its holdings in northern West Virginia.

A meeting of the stockholders of the Killarney Smokeless Coal Co. of Killarney; the Ingram Branch Coal Co., of Ingram Branch, and the Smith Pocahontas Coal Co., of Caloric, was held at Lynchburg, Va., about the middle of March, when Green H. Nowlan, of Lynchburg, was elected to succeed the late James Gorman as president of the three concerns.

M. M. Tyree and associates, of Huntington, who recently organized the M. M. Tyree Coal Co., with a capital stock of \$100,000, have moved into offices in the Robinson-Prichard Building, in Huntington, about the middle of March.

The Lawrence E. Tierney Fuel Co. has moved its general office from Powhatan to Bluefield.

The Wysong-McCoy Coal & Land Co., with extensive coal and timber holdings in Webster County, on the Baltimore & Ohio R.R., has been reorganized as the Multi-Seam Coal & Land Co. and arrangements are being made to refinance this company and put it on a sound running basis, according to news from the general office of the company at Princeton. S. J. Evans is president of the reorganized corporation.

Employees are to be given the opportunity to buy stock in the Bethlehem Mines Corporation, a subsidiary of the Bethlehem Steel Corporation, which marks a new departure in the policy of the mining company at least in so far as the Barrackville and Dakota mines, in the Fairmont region, are concerned. The plan is to be known as the "Employees Saving and Stock Ownership," by which an employee may subscribe for shares of stock at the rate of one share for each \$400 annual earnings. The price on the first year's offerings will be \$94 per share. The plan makes provision for credits of dividends and interest charges that will result in a net cost to the employee substantially below the purchase price. As an added incentive to employees to hold the stock and to continue in the employ of the corporation, it has been agreed to make special bonus payments every year for five years from the time stock is purchased, amounting to \$1 per share for the first year; \$2 per share for the second year and so on up to \$5 per share at the end of the fifth year.

Rumors of a sale of the Simpson and Galloway mines, three in all, and of 2,700 acres of Pittsburgh coal land in Barbour and Taylor counties by the Simpson Creek Coal Co. to the Simpson Creek Collieries Co. have been confirmed by an announcement made at the annual meeting of the first-named company. The officers of the purchasing company are identified with the Hanna interests of Cleveland and with the Youghiogheny & Ohio Coal Co. of that city.

John J. Lincoln, one of the well-known operators of the Pocahontas field, has invited the American Institute of Mining and Metallurgical Engineers to visit the Pocahontas district on its annual tour next October.

The Rosebud Coal Co., of Clarksburg, and the Gilbert-Fairmont Mining Co. have just been organized by virtually the same interests, the former company having a nominal capital and the latter \$50,000. Active in organizing the Rosebud company were J. M. McDonald, of Cincinnati; D. Kinnard, Karl B. Kyle, C. M. Barnes and L. J. Shahan, of Clarksburg. Incorporators of the Gilbert-Fairmont company were H. F. Mannix, of Cincinnati; K. B. Kyle, James A. Laislip, C. M. Barnes and L. J. Shahan of Clarksburg. W. VA.

Milburn By-Products Coal Co. at Milburn is installing a Roberts & Schaefer revolving dump and belt conveyor machinery.

The Meriden Smokeless Coal Corporation has just been organized with a capital stock of \$250,000 and with headquarters at Elkins and Meriden. The names of E. A. Bowers, William A. Arnold, Bertram Berger, G. B. Southward and A. H. Hoefar, all of Elkins, appear as incorporators, some of them being connected with the West Virginia Coal & Coke Co.

Latest information concerning the organization of the Meriden Smokeless Coal Co., capitalized at \$250,000 is to the effect that this simply represents a reorganization of the Albert Thompson interests and is for the purpose of giving title to the estate. W. H. Cunningham, of Huntington, has been elected president and Lee J. Sandridge of Philippi vice-president and general manager. The company operates at Meriden.

Of the total of 70,188,203 gross tons of coal produced in the mines of West Virginia in 1922, it is shown by the report of the State Department of Mines that there was produced of the Monongahela series, No. 15, a total of 14,652,987 tons; of the Conemaugh series No. 14, or Elk River, series a total of 1,916,895; of the Alleghany-Kanawha series No. 19, a total of 24,195,779 tons and of the Pottsville-New River-Pocahontas series No. 12, a total of 29,422,542 tons. Production in the same year by geographical districts was as follows: Panhandle, 3,796,904 gross tons; Fairmont district, 9,625,112 gross tons; Preston-Barbour district, 3,066,657 gross tons; Elk Garden, 1,080,042 gross tons; Mason, 48,253 gross tons; Putnam, 170,552 gross tons; Kanawha, 6,110,150 gross tons; New River, 11,900,162 gross tons; Logan, 13,904,980 gross tons; Pocahontas, 18,354,975 gross tons; Mingo, 2,130,416 gross tons; small wagon mines, 700,000 gross tons.

Fourteen resident and one non-resident coal corporations were organized in West Virginia in January with an aggregate capital stock of \$3,055,000, as follows: Agee Coal Co., of Huntington, \$200,000; R. S. Smith Coal Co., of Huntington, \$100,000; Gilbert Fairmont Mining Co., of Clarksburg, \$50,000; Rosebud Coal Co., Clarksburg, \$50,000; Brockman Smokeless Coal Co., of Charleston, \$300,000; Monarch Smokeless Coal Co., of Bluefield, \$400,000; Bonafield Coal Co., of Tunnelton, \$125,000; Braxton Fuel Co., of Clarksburg, \$25,000; Miners & Consumers Coal Co., of Huntington, \$275,000; Mine-to-Consumers Coal Co., of Martinsburg, \$25,000; Otter Creek Coal Co., of Hambleton, \$5,000; Dry Fork Sewell Coal Co., of Clarksburg, \$25,000; Meriden Smokeless Coal Co., of Meriden, \$875,000; Kistler Coal Company of Kistler, \$550,000; Sanderson Mining Co., of Greensburg, Pa., \$50,000.

WASHINGTON, D. C.

The Navy Department awarded contracts for 24,600 tons of navy standard coal to be delivered in April, May and June to the Government Fuel Yard, at Washington, to the Lake & Export Coal Co., at \$2.22 net mines; Raleigh Smokeless Fuel Co., \$2.24, and C. G. Blake & Co., \$2.24, each taking an equal share of the contract.

CANADA

The outlook for coal mining on Vancouver Island is blue. Owing to the general slackness of the coal trade on Vancouver Island, the Canadian Collieries, Ltd., has closed its South Wellington mines and the Granby Consolidated Mining, Smelting & Power Co. has reduced the working crew at its Cassidy Colliery 50 per cent. It is steadily replacing smelting with concentration, thus reducing its coal needs. Some of the men at the South Wellington mines are being given employment at the Wellington Extension mine. Unless some other outlet is found for the coal the cut of the crew at the Cassidy colliery is likely to be permanent. The bulk of the Cassidy coal is high in ash, and does not find a ready market. For smelting purposes, of course, it is crushed and washed before conversion into coke, so the high ash does not matter so much.

Gordon F. Dickson, general manager of the Blue Diamond Coal Mines at Brule, Alberta, has left for eastern Canadian points. Production at Brule has ceased since the discontinuance of coal orders by the Canadian National Ry.

The Pacific-Alberta Coal Bunkering Co., Ltd., has been organized, with an authorized capital of \$300,000, for the purpose of erecting coal bunkers for Alberta coal at Vancouver and possibly other towns on the British Columbia coast.

Association Activities

At the annual meeting of the Pittsburgh Vein Operators' Association, held at Cleveland March 11, Ezra Van Horn, general manager of the Clarkson Coal Mining Co., was elected president of the association, succeeding Michael Gallagher, of the M. A. Hanna Co., who had held the office three years. Mr. Gallagher led the association in difficult and intricate negotiations with the United Mine Workers and frequently was elected chairman of joint conferences for the whole central competitive field. Mr. Gallagher remains a member of the executive committee, representing the Wheeling & Lake Erie Coal Co. Walter I. Robinson, vice-president of the Youghiogheny & Ohio Coal Co., was elected vice-president. H. R. Sullivan, general manager of the Central Coal Mining Co., was re-elected treasurer. D. F. Hurd, who has been secretary for a number of years, was re-elected. The following members were elected to the executive committee: Mr. Van Horn, chairman; Mr. Gallagher; Mr. Sullivan; A. W. Dean, secretary-treasurer of the Barton and Fairview coal companies; J. L. Good, sales manager of the National Coal Co.; T. H. Johnson, secretary of the West Wheeling Coal Co., Bridgeport; J. C. Nelms, general manager of the Ohio & Pennsylvania Coal Co.; S. H. Robbins, president of the Youghiogheny & Ohio Coal Co.; C. W. Troll, president of the Troll Coal Mining Co.; Whitney Warner, vice-president of the Warner Collieries Co.; R. L. Wildermuth, vice-president and general manager of the Lorain Coal & Dock Co., Columbus; W. R. Woodford, president of the Rail & River Coal Co. Charles J. Albasin, labor commissioner, Bridgeport, was re-elected.

New Equipment

Drill for Cutting Circular Holes in Sheet Metal

A new tool is being manufactured for cutting circular holes in metal, wood or fibre by the Cincinnati Tool Co., Norwood, Cincinnati, Ohio. This device has knurled thumb screws which adjust the steel cutting blades so that the holes from 1 to 4 in. in diameter may be readily and accurately cut. The drill in the center is for the purpose of guiding the outer cutting blades so as to cut a true circle.

Drill for Cutting Large Holes

This device is designed for cutting true large size circular holes in metal, wood or fibre material. The long center drill is for the purpose of guiding the outer cutting blades.

Electric Power Trammer Readily Transferable

A small power driven caging device has been developed by the Mancha Storage Battery Locomotive Co. of St. Louis, Mo. It is known as the Mancha little trammer, and with it, mechanical haulage on every level of the mine is

made possible. It is built to run onto a mine cage like a coal car, and go to another level without the necessity of dismantling any part. By reason of its ingenious construction, one end of the locomotive, consisting of a bumper and seat for the motorman, can quickly be raised up over the top of the storage battery, thus shortening its total length.

When used in places where a spare battery is kept, this device can be used continuously by changing the battery. It does away with costly, inefficient mule haulage, or hand tramping, thus reducing cost and increasing tonnage.

The company is also prepared to furnish the necessary charging equipment for use with the trammer. Where alternating current is the only power available, motor-generator sets of suitable capacity are furnished with the battery charging panel.

Well-Balanced Centrifugal Pump

In the design of a new centrifugal pump it is always necessary to incorporate all points of excellence developed to date. The Moore Steam Turbine Corp. of Wellsville, N. Y., has just announced a new centrifugal pump in which they have incorporated several points of excellence.

This pump is designed so that rubber sealing rings may be used on the impeller between the suction and discharge chambers, and also for the use of metal graphite packing instead of the ordinary packing.

The metal graphite packing rings rest lightly upon the revolving shaft, there is no pressure to retard rotation and spoil the drive shaft. This feature is especially important where the workmen are not skilled in the care of pumps.

The pump is horizontally split, and perfectly balanced. Part of this balance is accomplished by placing the two impellers of the two-stage pumps in such a position that they will be back to back. The steel shaft is protected by brass sleeves. The pumps are suitable for motor, turbine, or belt drive.

Air Cooler for Generators.—The Griscorn-Russell Co., Massillon, Ohio, Bulletin No. 1216, "U-Fin Cooler," illustrates and describes a cooling device especially suited for turbo-electric generators. It is a surface type air cooler set in an enclosed duct, the air being used over and over again in cooling the windings. The cooling air is thus dry and free from dust, and in the event of fire in the windings, the oxygen in circulation is soon used up and the fire extinguishes itself.

Centrifugal Pump

The metal graphite packing rings provided with this pump rest lightly upon the revolving shaft and are not effected by heat or moisture, thus it is possible to operate the pump with the minimum amount of leakage. These pumps are now built with either one or two stages.

Instruments, Electrical.—Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa., Circular 1664, describes indicating instruments for direct and alternating currents.

The introductory chapter of the booklet includes a brief and interesting resume of the development of electricity with special reference to the development of alternating current and the earlier alternating-current instruments.

The research that resulted in these new instruments began with analyses of all activities requiring the use of electrical measuring instruments, and all the known principles of operation and construction. In the second chapter the story of this research is related, and there, also, are discussed the principles of operation and construction of the instruments as they are now manufactured.

The remainder of the book is devoted to the instruments themselves. One chapter dwells on questions of standardization and sizes, insulation, compactness, readability, sturdiness, accessibility, simplicity, damping, accuracy and calibration. Another chapter offers a detailed description of the parts making the completed instrument. The last chapter is devoted to instrument applications. According to the company, these instruments work at a very low maintenance cost.

Power Driven Car Trammer

This illustration shows the bumper and motorman's seat in the normal operating position. When the trammer is to be taken to a new location this bumper and seat is turned on its hinges to a position on the top of the locomotive. This arrangement shortens the over-all length

That Blind Spot

EVERY eye has its *punctum cæcum*, its blind spot, the point which affords no vision, and similarly every man has one or more mental inhibitions. Probably if Napoleon with his administrative ability had tried to do the work of Faraday he would have failed. That errand boy and retort washer looked out through what, to Napoleon, was probably only a blind spot, and he discovered the art of generating electricity by motion. Many a man has today administrative ability, even engineering ability but only a relatively blind spot or at least a point of obscured vision for electricity.

Unfortunately, he tries to be a universal mining genius and endeavors to operate his mine without an electrical engineer, suffering all the time because he has not courage enough to admit that electrical engineering is not in his line. Many a mine is hampered because some man in its management is incapacitated by some mental shortcoming and will not get help and advice from someone who has a preference for what creates in him merely a distaste. Fortunately most companies have realized this, and as a result are getting good results by delegating their electrical or their mechanical details to someone who has a penchant for such problems. Some still there are which try to find men of a universality of genius, but these men are hampered even if they do find them, for any man who attempts to cover every field thoroughly and to control everything is too busy to do anything well or fails utterly in a comprehension of some one or more of his many diverse duties. Thus we get plants which reflect the mind of one man and not the combined genius of several.

Marvelous or Only Inevitable?

“WHY is the coal industry so disturbed by labor troubles?” asks the man on the street. Let us look at the postal service for an answer. Some time ago the cost of living rose rapidly, but the U. S. Government failed to recognize that fact with sufficient clearness and failed to raise the wages of postal employees, so the latter banded themselves together to obtain justice. They could have left the service—some of them did—but most of them stayed and sought by agitation to get increases in wage.

Whether because it was necessary to pay more to get employees or because of union pressure or because of a sense of justice—who shall determine?—the rate of pay was increased. Possibly all three causes combined to effect the result. However, whatever the cause, in 1920 wages were raised, and the change in rates cost \$63,000,000 to the nation.

Today the postal clerks and carriers are getting \$1,400 to \$1,800 yearly, fully more than half of each class getting the larger stipend. They start in with the lower figure and rise in five years to the higher level and then, unless they become of a special grade and super-

wise other clerks, they continue to receive \$1,800 a year. That is a wage larger than that paid to employees of like character in private industry, as an investigation has proved. It is far more than is paid in country districts.

One would think the postal clerk and mail carrier would be satisfied, but they are not. There is the union for one reason. It is necessary that any man you are employing shall do something for you. If he isn't busy serving your interests you are defrauded. He must earn his wage. So the union must try to do something, just as it does in coal mining. Furthermore if you got an increase of \$63,000,000 by united effort in 1920, why not duplicate that or do better in 1924. Once the habit is formed it is not easily broken. We often have seen that state of affairs around the coal mines. “It has been done before, why not do it again?” is the well known expression.

Then again, the public is friendly. The people are writing letters to congressmen advocating an increase to postal clerks and carriers. In the coal industry we have seen a similar condition. The public is kind hearted. It likes to expend what it believes is another man's money. How bitterly it cries when it finds that it is its own.

So the clerks and the carriers are clamoring for a living wage just as the mine workers have clamored, and, just as there are too many men willing to “starve” as miners, so there are many men willing to “starve” as letter carriers and postal clerks. Over 6,000 men are certified as eligible for the service, having passed their examinations, but so far there is no room for them. Over 15,000 have written the Civil Service Commission asking when there will be another examination. So with little unemployment in the country, except around the coal mines, there are plenty of men anxious for these jobs.

The incentives are organized agitation, the hope of doing a second time what already has been done before and the good will of the public. This explains why the postal clerks and the carriers are fussing; it also furnishes a reason for the constant labor troubles of the mine workers. The U. S. Government says it can't pay the increases in wage that are demanded, for if they are paid the money must come out of increased postal rates or taxes. That answer seems insufficient.

If wages were inequitable or would not attract the men needed, there would seem to be ample reason for demanding that the money be found somewhere, even the \$123,000,000 which the Kelly-Edge Bill would demand in its first year and the \$150,000,000 more or less that in all would be required later. But the wages are not inequitable nor are men scarce, so the readjustment should not be made except perhaps in large cities where rates and other living costs are inordinately high.

The gods in the gallery are laughing however that the Government which has meddled so often in mine labor difficulties and has sobbed so loudly that the operators and miners could not solve their differences

promptly and amicably has now a trouble of its own and finds that with agitation becomes a business and with protest raised to a practice and with a populace willing to sympathize with wage earners, right or wrong, disputes are chronic. No sooner is one settled than another starts.

Alex Howat Is Not Dead

SOME things that have been going on down in Kansas indicate that the Alex Howat issue is by no means dead within the United Mine Workers. The forcible ejection of Howat, deposed former president of the Kansas union district, from the Indianapolis convention of the union did not strengthen President Lewis in the estimation of many Kansas miners. Instead, it excited them so that Howat was considerably in the ascendent at the recent Kansas district convention. What he demands is reinstatement in the union with full and immediate rights to hold union office and attend international union conventions.

It is plain that if the Kansas district had the power it would give him what he wants. But, unfortunately for Howat, the district has not that power. In its convention the district went on record in favor of abolishing the rule that after a union man has once been expelled he cannot, for three years after reinstatement, hold office. It appears obvious that if it were possible for the Kansans to reinstate Howat and nominate him for election to the presidency of the district, he would certainly be elected in spite of what President Lewis could do to prevent this disturber from getting back into control in the Southwest.

The district convention wanted to pay Howat for the five months which elapsed between his expulsion for calling an unauthorized strike and the end of his term. Lewis may bluff the Kansans out of this with his threat that he will prosecute them for misappropriation of union funds. But the fact remains that Howat is not dead in his own stamping ground and without doubt will continue to harass Lewis from outside the union.

Your Place in Cincinnati

AMONG the misfortunes of executives is the fact that in conversing with their subordinates they are prone to start the conversation and not always wisely. The subordinate puts in an idea here and there to round out the detail of the picture that the executive draws, but it is on the whole the executive's picture and not the subordinate's, and if the executive is disposed to follow the practice at some other man's mine there is little the subordinate can do to get a wholly new method of operation adopted.

The time is here for radical changes. You can no longer be content to follow old courses with trifling modifications here and there—modifications within the authority of subordinates. You must get a new vision or you face a deficit, and if you cannot see one you must get with other men who perhaps can; you must battle with first principles rather than box with trifles.

This is what makes the Cincinnati meeting different from the meetings that have preceded it. It is to deal with fundamentals. It is to widen concepts. Men without travel, without discussion, fall in a rut. Cincinnati will be outside that rut. Executives and engineers will meet to find a new way; they will meet more numerously than ever. The darker the night, the greater the need of light.

"Stay at home and save money" is foolish counsel. "Travel and learn a better, more economical way" is better advice. Go to Cincinnati prepared to find an answer to the troubles that perplex you. Have your subordinates meet you there. See that they absorb all that offers. Encourage them to give their views. Have them make their reports and listen to their counsel, prepared to follow or reject it as your judgment directs.

Your progress depends on using the best your assistants can devise, in giving your subordinates the information on which to direct their judgment. Time devoted to study and business contacts is not lost, it is invested. If you are at the Cincinnati show, you will be able to see that the time expended, by your staff, is well spent, and you can profit by the repercussions of other minds, of fellow operators, of superintendents, of engineers and of your subordinates.

"On to Cincinnati for lower costs per ton."

What About Western Kentucky?

MR. LEWIS and the international union have a job on their hands in western Kentucky, for that field is nearly lost to the union. In some of the other outlying fields, notably in the far West, it has been able to continue the expiring agreement for three years as was directed from Jacksonville, although it must not be overlooked that the scale in the state of Washington was at least \$1.25 a day less than that in the Central Competitive Field. But in western Kentucky the situation is different. That field is much closer to regular \$7.50-a-day union territory and therefore the course of unionism there is important.

As the situation now stands, western Kentucky is already divided between unionism and the open-shop. The western half of the region is covered in spots by a contract signed at Madisonville a year ago and which runs another year. Several important companies have not been operating under it but have paid approximately the contract scale which called for 90c. an hour to machine runners, \$6.59 to \$7.20 to other inside labor and \$6.06 to outside labor.

In the eastern half of western Kentucky negotiations are now on for a new contract to replace the old one, the duration of which in consequence of the deadlock between miners and operators has been extended from April 1 to April 15. There the operators demand a 25-per-cent reduction and insist on it in cold terms. The weakness of the union's hold on even this part of the field is such that district-union leaders well know they cannot compel every operation to sign a continuation of the old contract. If Lewis is determined that his Jacksonville ultimatum to outlying districts must be obeyed by the union organization in western Kentucky, then unionism is dead in the whole field.

The question is, will Lewis manage to devise some sort of compromise when the district organization has failed to do this very thing in two weeks of negotiation? or will he cave in and officially sanction a wage reduction of 25 per cent to save the union's skin. Of course he has already been consulted in the western Kentucky matter, and since a stay of fifteen days has been agreed upon, it is logical to suppose that Mr. Lewis is putting off surrender as long as possible so as not to prejudice the case against the union in the Southwest where the operators demand relief and where in order to get it, they are ready to shut down the field and keep it shut down if it takes all summer.

Limitations and Eccentricities Of the Beckley Coal Bed And How Best to Offset Them*

Usually the Upper Split of the Bed Is Worked and This Is Extremely Uneven in Contour Making, Pumping, Haulage and Supervision Problems Severe and Standardization Difficult

BY C. R. STAHL
Glen White, W. Va.

BECKLEY coal was named from the town of Beckley, in Raleigh County, West Virginia, the point where it is most extensively mined. Assuming the Fire Creek seam to be a separate measure, the Beckley bed is the lowest commercial bed, but one in the New River group which forms part of the Pottsville series.

The interval between the Beckley and Fire Creek seams often thins so that the two form one bed, according to the correlations of investigators of the West Virginia Geological Survey, whose conclusions are provisionally accepted and adopted by the authors belonging to that organization. Recent core-drill records, however, tend to upset this theory and convince its opponents that the Beckley seam is a peculiarly eccentric geologic formation composed of two parts, the lower split always lying in its true position with regard to other coal beds of the series adjacent, while the upper split varies from its regular position directly over the lower one, to intervals that baffle all methods of accurate determination in advance of mine development.

The commercial value of the Beckley bed in the past has lain in the top split. Still the lower split has its value. In some places where the parting is thin or has disappeared entirely, the two splits are worked together. A few mines also are working the bottom split where the top split is too thin to mine. Furthermore, there is reason to believe that the splendid coal deposit

now being developed in the Laurel Basin in Wyoming County is the bottom split of the Beckley instead of the top split as has been heretofore supposed.

Beckley coal varies in thickness from 0 to 12 ft. and has been correctly described by the West Virginia Geological Survey as a multiple-bedded, soft, columnar coal. The principal overlying strata is a massive current-bedded sandstone varying in thickness from 50 to 100 ft., and named by Dr. I. C. White, State Geologist, the Lower Raleigh Sandstone.

Underneath this sandstone, and separating it from the Beckley coal bed is a dark-gray argillaceous shale varying in thickness from 0 to 17 ft. A typical analysis of the Beckley coal in its pure state is given in Table I:

Table 1—Analysis of Beckley Coal

Moisture.....	0.88	
Volatile matter.....	17.37	
Fixed carbon.....	78.25	
Ash.....	3.50	
Total.....	100.00	
Sulphur.....	0.53	
British thermal units.....		15,095
Phosphorus.....		Negligible
Fusing point of ash.....		2,600 deg. F.

The thickness of this coal, its purity and excellent heating qualities make it a highly desirable fuel, and long ago it established itself on the market as one of the finest steam coals in the world.

As yet no coal of merchantable value has been found in this bed along New River. It begins to assume commercial proportions in the deep canon of Piney River, in the vicinity of Stanaford Branch, and from there

*Paper read before the West Virginia Mining Institute.

south-westward, it is a seam of great value, forming as it does the bed from which the great Winding Gulf coal field has received its reputation.

In the southern zone of that field the Beckley coal is mined chiefly from drift openings, while in the northern portion it is produced principally from shafts of varying depths. Approximately 1,250,000,000 tons of this coal remain to be mined in the areas now under development in Raleigh and Wyoming Counties.

Fig. 2 shows a longitudinal section developed along a line beginning at Thurmond, W. Va. (See Fig. 1) and extending S. 28 deg. W. The section line passes through the city of Beckley, crosses the Winding Gulf at Hot Coal, touches Stone Coal at the mouth of Tommy Creek, and crosses the main line of the Virginian Ry. about $1\frac{1}{2}$ miles northwest of Herndon. At this point the Norfolk & Western coal fields are reached. The line above referred to crosses Elkhorn Creek at the town of Northfork, touches Tug River at Pageton, and crosses this stream just east of the Black Wolf coal-mining plant.

A glance at the longitudinal section, Fig. 2, will show the relative positions of the Beckley, the Sewall, and the Pocahontas No. 3 and 4 beds which latter up to this time have been the major commercial seams of the Pocahontas group.

The relation of the Beckley coal to the principal valleys in the Winding Gulf-New River area as well as the relation of the Pocahontas No. 3 and 4 beds to the valleys in the Norfolk & Western zone are plainly shown on this section, and indicate the accessibility that determines the methods followed in attacking the deposits in the different fields.

Peculiarly enough, the Beckley bed, which is the

major producing measure in the Winding Gulf field, is underlain with the thin and sometimes laminated Pocahontas No. 3 bed throughout that region. On the other hand, the Pocahontas No. 3 becomes the major bed in the Norfolk & Western field, the Beckley, or War Creek seam, which lies high up in the mountains, becoming in that area a thin and laminated bed. It seldom happens that both the Beckley and Pocahontas No. 3 beds are found in prime condition on the same lease.

Prospecting a lease for Beckley coal should be placed in the hands of parties experienced in that particular bed; otherwise a prospective lessee stands a chance of losing a good lease by reason of insufficient and improperly placed drill holes; or on the other hand, a lease may be taken up and a costly plant installed, only to meet conditions so faulty as to wreck the mining venture. Examples of both conditions can be found in the territory where the Beckley seam is worked.

The vagaries of the Beckley seam that confront the prospector become the problems of the operator. The producer's real troubles might thus be said to begin at the drift mouth or shaft bottom.

The general dip of the coal is nearly due northwest on an inclination of about 3 deg. It seldom happens, however, that a new mine can be projected with regard to this general dip. Usually the drills show a local dip with the inclination extending over a sufficient area to justify laying out the mine in accordance with it. Rarely indeed can the original mine projection be followed to its conclusion. Fortunately, the Beckley coal is so soft that it can be worked equally well in any direction regardless of the face and butt cleats. In consequence, the projection can be changed at will.

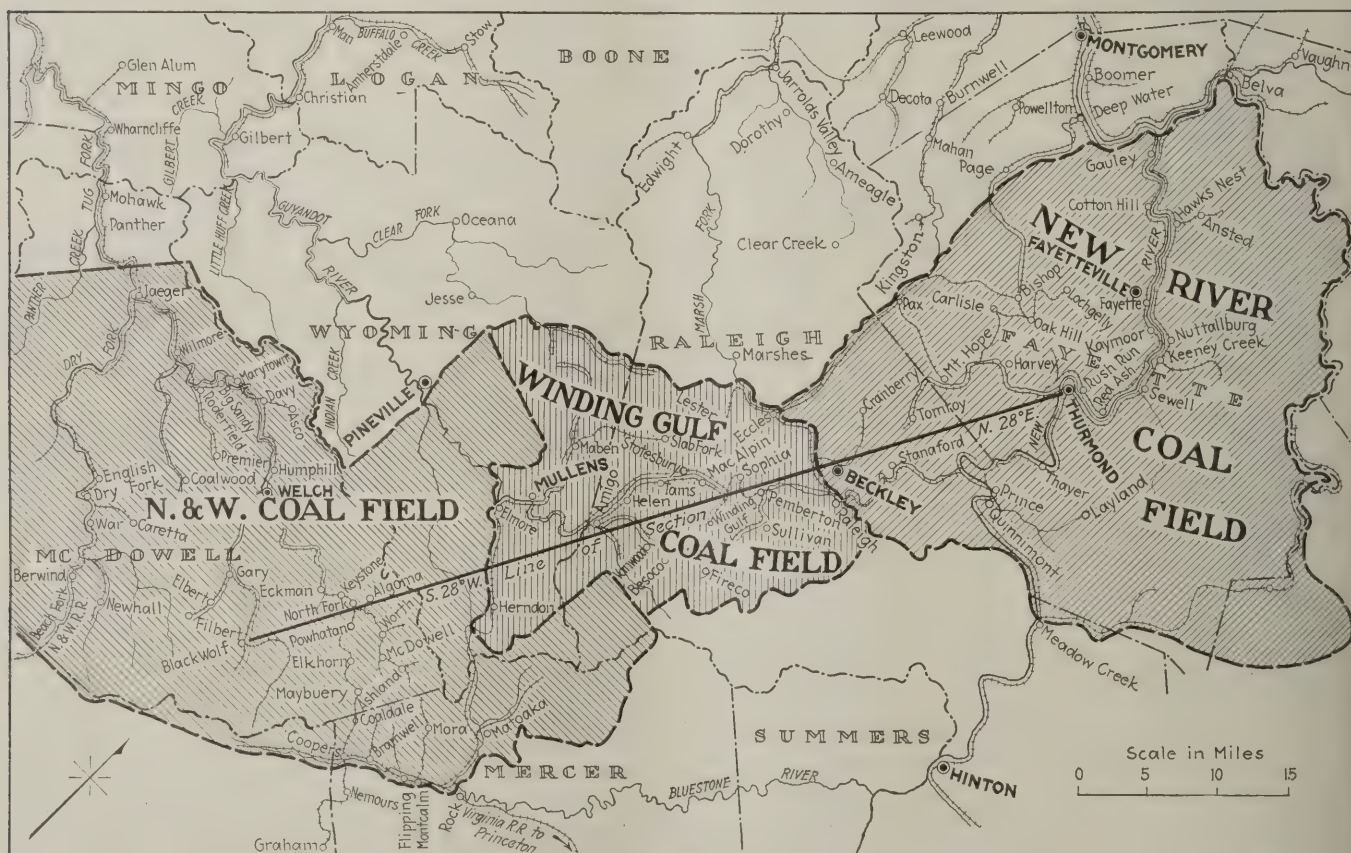

Fig. 1—Map of the Region Where Beckley Coal Is Found

The line extending from Thurmond to Black Wolf is the line upon which the cross-section shown in Fig. 2 is taken

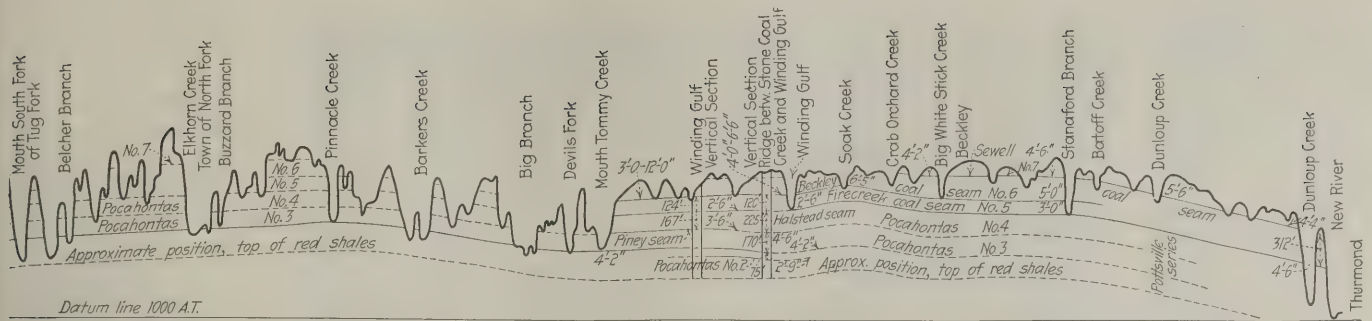

Fig. 2—Cross-Section of the Region Where Beckley Coal Is Found

This shows the Beckley bed not only in relation to the other coal deposits of this region but also to the surface. It is a strange coincidence that where the Beckley bed is most workable the Pocahontas measures are of poor quality and vice versa.

In opening a new mine in this coal bed, particularly if it be a shaft mine, it is well to make only a temporary main pumping installation and to provide only temporary pumping room. The permanent layout around the shaft bottom should be delayed until sufficient development proves what is the most favorable location.

In the past the operator mining the Beckley bed has usually not made sufficient allowance for the temperamental mood of Dame Nature. He has opened up his mine in a basin of clean coal, often ignorant of the fact that the local variations mentioned were present. He has started out with favorable grades and good top, these conditions continuing in some cases over an area of 200 or 300 acres. He has built himself a reputation and made money for his stockholders.

For this man there has been a day of sad awakening. He will have bought his equipment for mining thick coal, but will find some day that his entries have been driven into places in the seam that do not suit such equipment. He may then, if bold enough, change the character of his equipment to meet the new conditions; or, he may, as many have done, shoot bottom in his rooms, maintain his tonnage as long as he can, sell his mine, get a new job and leave someone else to work his way out of the difficulties.

This bed as it changes from thick to thin, varies also to some extent in character. In the top split of the Beckley bed, which is the split usually mined, there is a characteristic gray band consisting of low-ash coal located about $3\frac{1}{2}$ ft. from the top. In thick coal this may be loaded out with the rest of the mine product and sent to market. When the coal gets thinner, however, this gray band thickens and becomes a hard bone, that must be separated from the coal, either in the working places or at the tippie. One thing may be said for the Beckley bed, in this connection, however; it is usually possible to send it to market without any other preparation than hand-picking.

As the entries go to the dip, the coal thickens; as they go to the rise, it thins. It is the rule rather than the exception to find the extremes of these two conditions within a thousand feet of each other with the grades varying from level to 12 or 15 per cent.

Another variable is the character of the top. Where the coal is thin, say from 3 to 4 ft. thick, the top is nearly always a hard sandstone. It sometimes is broken up and mixed with a little slate and coal; but it is probable that this portion of the measure will lend itself to longwall mining. With about 4½-ft. coal we have a top that may be either sandstone or shale. It may be good with no drawslate, or it may be consistently bad, with 3 ft. of that material ready to fall. The character of the bottom in this thickness, however, is

such that pillaring is easy. And I would say also that this represents the Beckley bed in its best average condition.

Where the coal is thick the top may be slate, it may be shale, or it may be hard sandstone. However, the bottom is usually soft, making pillaring rather difficult. It is impossible to make a room-and-pillar system applicable to all of the changing conditions of the Beckley bed. Consequently, the width of the rooms and the thickness of the pillars should be altered to suit the conditions found.

It will be seen that the conditions outlined make main-line haulage difficult. I know of one mine that, in re-shooting its main entry after this passage had been driven in a mile, could do no better for a distance of 2,600 ft. than establish a grade of 3 per cent against the loads. The power cost of mining Beckley coal is

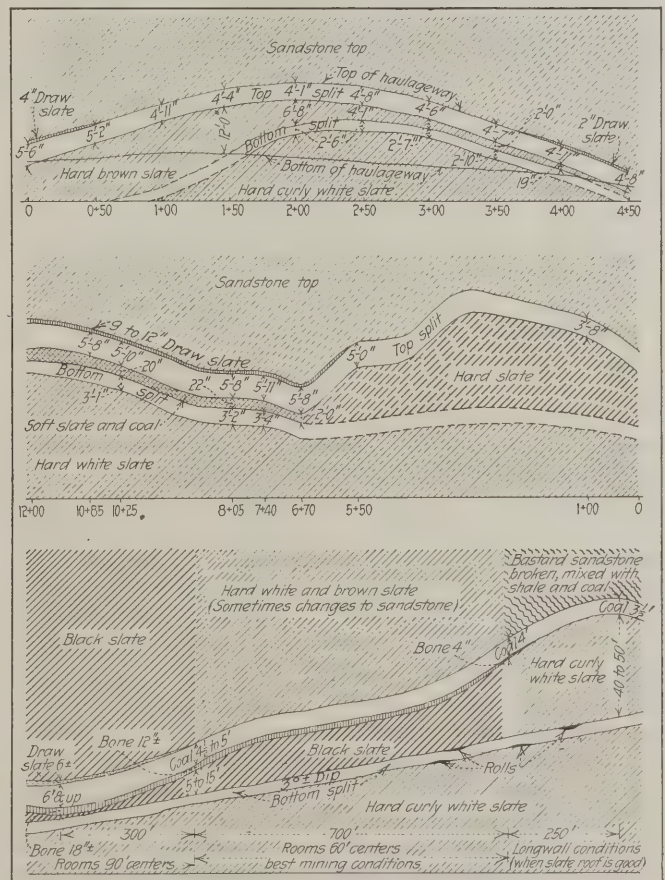

Fig. 3—Typical Cross-Sections of the Beckley Bed

Sometimes the top and bottom splits unite and form one coal bed. More often, however, the splits are distinct. The bottom split is far more regular in contour than the top split which is almost remarkable for its irregularity.

FIG. 4

A Shaft Mine

The Upper Split is the one usually worked but it is so uneven both in thickness and contour that much dead work must be done. Pumping is a difficult but not a serious problem, and it is frequently impossible to project advance workings and adhere to such a projection.

naturally high, and the wear and tear of the machinery used is heavy. It is probable that the repair bills of the Beckley operator are two or three times as high as those of operators working coal measures on uniform grades.

The operator can provide for future haulage and mining in only one way if he desires to maintain tonnage and show a cost that will have bad conditions distributed along with the good. This is to keep the entries three or four years ahead of any known requirement. By this means he is enabled, when he shoots slate for height and grade, to do so intelligently and to lay out his work in each section of the mine for two or three years with the advance knowledge gained from having the territory developed by entries driven as mentioned. This means, however, that he will have thousands of feet of development open at all times upon which he receives no return. Air currents must be maintained in these sections; and airways must be kept clear of falls; furthermore gas must be swept out.

Cutting and shooting, fortunately, do not present any particular difficulties. The coal is mined, where thin, with shortwall, and where thick, with arc-wall machines. Pick mining in the Beckley bed, like mule haulage, is a thing of the past. Sometimes the coal will be "burned" to the bottom or to the top, making shooting and scraping difficult. In this respect, however, the Beckley bed, by and large, presents no great obstacles. Heavy grades, however, cause excessively heavy wear and tear on the cutting machines, as they must go where conditions are bad as well as where they are good. Machine runners also must be skillful, so that they may direct the cut to the dip or to the rise or on a side pitch, as the conditions encountered may demand.

Another difficulty encountered in working the Beckley bed is found in the variable thickness. The mining man likes to use thick-coal equipment for thick coal and thin-coal equipment for thin coal. The thickness of a bed does not in itself mean either smaller or larger tonnage. There are mines in the vicinity of Windber, Pa., that produce large tonnages from thin beds. Such mines, however, are equipped for doing so. The Beckley operator, on the other hand, is confronted with the choice of working thick coal equipment in thick and thin beds alike, or of employing thin coal equipment in both thin and thick measures. He may, of course, use thick coal equipment in his thick coal and thin coal equipment in his thin coal, but these conditions are

local and change so rapidly that he soon has some equipment in a section of the mine not suited to it.

Ninety-five per cent of the Beckley coal now produced is mined by the room-and-pillar system, and it is unlikely that more than 30 per cent can ever be mined successfully by any longwall method. When, therefore, the Beckley operator attempts to use a loading machine, he must adopt a device that will work in room-and-pillar mining and in variable thicknesses of coal, but which can be transported over heavy grades.

WORKERS OUTPUT ALSO VARIES GREATLY

Not only must the variability in the coal bed be considered but also the variation in what constitutes a day's work. The standardization of mining, which is much to be desired, can hardly be accomplished in the Beckley bed. Motormen, machine-runners and tracklayers can do more work under favorable conditions in thick coal than under unfavorable conditions in thin coal; but it is difficult to secure this extra accomplishment from the men. The motorman's idea of a day's work is all too likely to be established by the motorman who labors under unfavorable conditions in thin coal.

The motorman working in the thicker sections, as well as other day men, is prone to believe that if he gets as many cars per day as the other fellow, he has accomplished his day's stint. The man in the thin coal, however, is constantly trying to get a job in thick coal, whether he be motorman or tracklayer; and if he is held to work in the thinner place is likely justly to consider that he should gather fewer cars and lay less track than his brother in the thicker coal. In considering the work that he might legitimately be called upon to perform, he is more apt to do too little than too much. Likewise, the loader wants to work in the thick coal, and a high differential has to be paid him in order to induce him to stay in the thinner place. As indicated elsewhere, the thinner portions of this bed will likely be worked in the future more and more by means of mechanical devices.

All of this means that the supervision given to mining in the Beckley bed must necessarily be of a high order, and that it takes constant vigilance and hard work to secure reasonable efficiency from the men. This combined with the fact that conditions constantly change, necessitating alterations in plans and methods of mining, is apt to result in a high cost for day labor in producing this coal.

Countless swags encountered in this coal measure entail big pumping bills, numerous pumps, many pump-runners, and high repair charges. The quantity of water found in any one swag is not excessive as a rule, but it is a continuous source of trouble unless expensive drainageways are driven to draw it off. The bottom split of the bed is nearly regular and usually too thin to be worked on its merits. The drainageways can usually be driven in it to tap the swags that are found in the top split. Many miles of such drainageways have been driven in the Winding Gulf field.

Swags usually occur where the coal is thick and the bottom soft. In many instances the bottom will begin to heave in these swags before any pillaring is done, the water appearing to have a softening effect on the slate. The wise operator, therefore, in pulling his pillars, will

mine out the swags first. And here again he is confronted with the difficulty that every pillar job has to be planned separately from every other; no systematic method, to be followed throughout the life of the mine, and to which the men can be trained, is suited to the Beckley bed. Here again we have another necessity for the high order of supervision given to mining and the large number of bosses required, all of which adds to the expense of operation.

In conclusion let me say that the man who wishes to make a success of mining this splendid, if irregular deposit of coal, must have ample capital. He must be prepared to stand hard knocks, and spend considerable sums of money in overcoming at the outset any adverse conditions that may be encountered never letting them accumulate to overwhelm him later.

Six Per Cent of Methane Makes Mine Air Dangerously Explosive

At Low Limit Methane Propagates More Readily Up Than Down—Air Vitiating by Carbon Dioxide Explodes Only When Methane Content Is High

"ONLY in percentages between 6 and 14.6 is methane dangerous," said Dr. R. V. Wheeler, director of the Mines Department of the Government Experiment Station, Eskmeals, Cumberland, England, in addressing a body of mining men at Scranton, Pa., March 20. Dr. Wheeler said that though the explosive action of methane is entirely unaffected by the intensity of the source of ignition it does depend in an important degree on the position of that source.

An explosion of methane at its lower explosive limit will propagate more readily upward than downward. The flame rises more readily into the stratum above it and propagation is thus made easy. If a 5.3 per cent mixture of methane and air is ignited near the floor of the mine it will burn upward slowly in a long column and without spreading till the roof of the mine is reached. Then it will spread laterally slowly for some distance without any speed or violence. With 5.4 per cent of methane the flame will involve the whole area containing the gas providing that area has that same percentage of methane and is ignited from below.

If, however, the proportion of methane is 6 per cent the firedamp will ignite and burn in all directions even when lighted near the roof. Similar phenomena may be noted at the upper limit of ignition. A firedamp having 13.4 per cent of methane will flare upward if ignited at the bottom. If the percentage of methane is 13.5, the firedamp will propagate flame laterally but not upward. If 14.6 per cent of methane has accumulated, the flame will extend its ravages downward but not upward or laterally. Any larger percentage of methane than that forming the upper limit will not propagate at all in any direction. These figures may be expressed in a table:

Explosive Limits of Methane in Air

	Lower Limit Per Cent	Upper Limit Per Cent
Upward.....	5.3	13.4
Downward.....	6.0	14.6
Horizontally.....	5.4	13.5

The stratum above a 14.6-per cent body of firedamp is vitiated by the products of combustion and will not burn. The stratum below it is free from that vitiation

and the flame will travel downward, not readily, but slowly. Dr. Wheeler declared that by the explosive limit is meant the point in percentage where a flame is self-sustaining. The combustibility of methane is an entirely different matter. The firedamp that is explosive is not merely capable of being burned but capable of burning without an exterior

source of combustion once it has been ignited. He put the danger limits between 6 and 14.6 per cent,

He fully agreed with the American point of view that trolley locomotives wisely might be permitted in mines where the air in the mine continuously could be kept well below the explosive limit. Henry Walker, the deputy chief inspector, who was accompanying him on his trip to America, might question, he said, that statement and in saying what he did he spoke for himself alone. The British regulations prohibited any but armored cables, but he believed that the British rules were too conservative, for the explosive limits were well known and never were any lower than the low limits stated.

Speeds of propagation vary from about 20 ft. per second to about 100 ft. At 9 and 9.5 per cent the speed of the explosion reaches a maximum. On either side of that maximum the propagation speed falls rapidly. At 7 per cent the speed is less than half that at 9.5 per cent.

Dr. Wheeler said that the explosive limits were narrowed where the air was vitiated by the presence of carbon dioxide. If only 14 per cent of oxygen instead of 20.9 as in pure air be present, the lower limit of upward propagation instead of 5.3 per cent becomes 6.2, and the lower limit of downward propagation becomes 6.4 instead of 6.0 per cent. The speeds given

George S. Rice and R. V. Wheeler

Mr. Rice says this picture was taken at Eskmeals, Cumberland, England, which shows that the sterile dunes of that region can show in places a little thrifty vegetation.

referred to explosions at the open end of a heading. They were greater where the explosion started at the far, or closed, end. The speed of propagation was a little greater where the roadway was large.

Where the explosion starts at the far end of a heading it becomes more violent as it progresses toward the open end. Hydrogen has explosive limits far wider than methane. They lie between 10 and 80 per cent. Dr. Wheeler said that methane ignited sluggishly. Thus glowing coals would not ignite firedamp if their temperature was below 600 deg. C. (1,112 deg. F.). No matter how hot the source, methane would not ignite unless it had been exposed to the flame arc for ten seconds. That was why the flame of "permitted explosives" as they were termed in Great Britain would rarely ignite firedamp. Black powder gave a flame of longer duration and was dangerous in consequence.

ANTHRACITE DUST CAN BE EXPLODED

Dr. Wheeler questioned G. S. Rice's statement that anthracite dust would not explode. Given a sufficiently violent source of ignition it would propagate flame, but fortunately, he added, such a source was not likely to be provided so no one in anthracite mines need be apprehensive of that form of hazard.

Henry Walker, deputy chief inspector of Great Britain, said that a gaseous mine was defined in the law as one where the methane in the return was normally one-half per cent or over, or where a man had been

injured in an explosion of methane. He said that to protect the lives of the men from falls of roof the mine-inspection department specified the distance between supports, between the rows of supports and between the rows and the face. He declared he could not approve the American anthracite practice of blasting out timbers but favored rather the use of prop pullers. A new device provided for the twisting of the prop as a pipe is twisted by a wrench. This seemed to give excellent results enabling the prop to be removed with ease.

Asked by E. T. Conner whether men should be withdrawn if the percentage of methane rose to $4\frac{1}{2}$ per cent, Dr. Wheeler said in such a case he would exercise every precaution, feeling fearful that the point from which the methane came would have an explosive quantity of that gas, but until he found such an explosive source, if he were a mine owner, he would not remove the men. Mr. Walker in further answer to Mr. Conner added that it would be his painful duty under the hypothetical case to prosecute Dr. Wheeler for violating the law which required that the men be withdrawn after $2\frac{1}{2}$ per cent of methane had been noted.

Prior to the meeting, which was held in the auditorium of the Scranton High School, E. T. Conner entertained the British delegation and a number of the principal engineers of the anthracite region at the Scranton Club. The meeting was held under the auspices of the Engineers' Society of Northeastern Pennsylvania with President Dimmick in the chair.

Crush Coal to Meet Market Needs

BY H. M. KILLMAN

Mining Engineer, Mount Olive & Stanton Coal Co.,
St. Louis, Mo.

The coal at our No. 2 mine is a high-grade bituminous steaming coal and the percentage of lump and fine coal cannot be adjusted to meet our contracts without some crushing device. For this reason we have installed an American coal crusher. The coal comes directly from the shaker screen to the crusher where the large lumps are broken by the impact of a series of rings. After the coal is crushed it is conveyed by a belt conveyor to the screens where it is sized and then delivered to the railroad cars.

Since the installation of the pulverizer, 140,000 tons of coal have been crushed. Although the equipment is capable of handling 350 tons of coal per hour, it has produced our requirements by operating about four

full days' time for four months of the year when its operation becomes necessary.

In order to take advantage of the market conditions at all times our company has found it advantageous to be always in a position to ship either lump or crushed coal. At times, the market for fine coal is better than lump, and when such a condition arises we crush enough of our lump coal output to satisfy the demands of our market.

Previous to 1918, the annual cost of crushing at our No. 2 mine at Williamson, Ill., was \$0.0643 per ton, but in that year when we installed the present equipment we reduced the cost to \$0.0195 per ton—less than one-third of the former cost. With this new apparatus we effected a saving of \$0.0448 per ton, or an annual saving of \$1,253.22 on an average of 28,000 tons crushed per year. Repairs to the crusher have not cost a single cent to date and the estimated life of the device is forty years.

Fig. 1—Efficient Coal Crushing Plant

When coal may be quickly crushed at the cost of only 2c. per ton, contracts for sized coal can be readily fulfilled.

Fig. 2—Crusher With Capacity of 350 Tons of Coal per Hour

The coal comes directly from the shaker screen to the crusher, the large lumps being broken by the impact of a series of rings.

Wood Preservation and Reforestation Advances Reviewed by American Mine Institute

Expenses of Replacement Make Use of Untreated Timber Inadvisable—Two Mines Take Advantage of Their Own Fungus-Killing Water—Almost Four Board Feet Used for Every Ton Mined

A SUBJECT which is daily becoming of more and more interest to mine owners and operators throughout the entire country is that of provision of the timber necessary to mining operations. As is well known, the original forest areas of this country have been largely denuded and the mines are consequently having to go farther and farther afield for their timber supply. A round table discussion of this topic was held at the recent annual meeting of the American Institute of Mining & Metallurgical Engineers and several interesting phases of this important problem were brought out.

There is no panacea or even palliative that is immediately available for the difficulties which the coal mines of the country are now facing in the way of timber supply. As was brought out in this discussion, however, there are three well defined methods whereby the present situation may be at least partially relieved. These are:

- (1) The use of less timber in mining.
- (2) The preservation through chemical treatment of the timber used, and,
- (3) The employment of various substitutes for timber.

USE 3,516,000 M. BOARD FEET YEARLY

No single one of these alternatives will solve the present problem, but the use of all three may go far toward alleviating it.

The use of mine timber throughout the United States has increased from 201,000,000 cu.ft. in 1905 to 293,000,000 cu.ft. in 1919. Of this latter quantity about 250,000,000 cu.ft. were used in the round form or as logs.

It was brought out that in the United States the life of untreated mine timber varies from a few months to as much as ten years, but that the average is only from three to five years. Furthermore, the cost of renewing a timber, whether in shaft or in gangway sets, is several times the cost of its preservative treatment. If by means of treating with preservative, the life of a timber is appreciably prolonged, the investment in such treatment is well justified.

As to the cost of treating mine timbers, this is something which varies with conditions. It was stated, however, that treatment by means of Aczol costs about 10c. per cubic foot, whereas treatment by means of other preservatives ranges from 10 to 90c. per cubic foot. The second largest item of expense in timber for the mines is that for track ties. On main haulage roads, these at least, are put in place and left undisturbed until they must be taken out because of decay.

Many preservatives are available to the American mine owner. Some of these are well known, while others are but little used. The best known preservatives are coal-tar products, such as creosote, and various chemical salts such as copper sulphate and zinc chloride. There are also various mixtures of these salts marketed under several trade names, the best known of which is the Aczol previously mentioned.

Several different methods of treatment also are available, but, in general, only three treatments are in use. The first of these is the pressure treatment wherein the wood is placed in a closed cylinder. The air is first exhausted and then the timber is flooded with preservative and pressure applied over a period of several hours. This forces the preservative into the inner pores of the wood. The second type of treatment is

Land Denuded of Timber with Tents Erected for the Accommodation of Tree Planters

Acres and acres of such land can be found. If we wait ten years to plant them, when the decade is past and lumber soars higher than ever, we shall wonder why we left the planting so long.

known as dipping, or soaking, and consists in immersing the timber to be treated in a tank of preservative for a certain period of time. The third type of treatment is known as "brush treatment" and consists in painting the outside of the timber with preservative by means of a hand brush or air spray. There is little question but that the pressure treatment of timber previously framed and made ready to be put in place gives the most lasting results.

Most European mines are using some form of wood preservative treatment for a large portion of their timber. As a rule, these mines prefer pressure methods. At least two American metal mines are soaking their timbers in the mine water to preserve them, the preservative effect of this soaking being probably due to copper salts held in solution by the mine waters of these mines. A treated timber is not subject to the attack of fungus as is one that is untreated. Furthermore, it is far more resistant to dry rot. Some European mines, as stated by Mr. Rice, are using a hot salt brine as a preservative.

WOOD IS MORE ENDURING THAN CONCRETE

Howard N. Eavenson said that in some shafts the concrete linings do not last as long as those made of timber. In western Pennsylvania, several concrete-lined shafts, which were supposed to be permanent installations made at a considerable expense, had failed in less than ten years. Most of these shafts are on in the intake air, but the exact cause of the failure of the concrete is not definitely known.

Underground, both concrete and metal timbers are used as substitutes for wood. In European mines, brick and stone masonry are employed to a certain extent as substitutes, although these fail under heavy pressures, particularly if the pressure does not come upon the supports uniformly.

In speaking on this phase of the problem, Mr. Rice stated that in Europe where heavy pressures must be resisted, I-beams bent in the shape of an inverted U were being extensively employed. These would deform to a certain extent under excessive pressure, but would not fail.

It was suggested that the United States Forest Service might well work out the comparative effectiveness of the dipping and pressure treatment. It was also stated that seasoned timber lasts much longer than green timber when used in the mines. Furthermore, that 24½ per cent of the timber used in coal operations might well be treated with preservative. The paper

contributed by Newell G. Alford which will appear later in *Coal Age*, stated that the net use of timber was 3.71 board feet for each ton of bituminous coal produced. This paper also stated that approximately 2,022,000,000 board feet of lumber was used in bituminous mines in 1923 and that the possibilities are that by 1940, this will increase to approximately 3,005,000,000 board feet.

As is well known painting does much to lengthen the life of timber used in surface construction. This is so thoroughly appreciated nowadays by mining men that no further mention need be made of it.

A national and state forestry policy is greatly needed in this country. The various states must be induced to pass statutes which do not conflict with national laws and which foster forestation. It was suggested that the American Institute of Mining & Metallurgical Engineers might well appoint a permanent committee on this subject in order to correlate information regarding it and foster interest therein. Some engineering bodies already have committees of this kind and each has a different viewpoint. Probably the State of Pennsylvania has gone further towards fostering the reforestation of mining areas than has any of the others. This state now furnishes trees for planting without cost. These consist mostly of pine, larch and ash. It takes about fifteen years to produce a three sufficiently large to make a mine prop.

Some mining companies, particularly those operating throughout the anthracite region, have already given much care and thought to the subject of reforesting their areas. In the bituminous region, however, little reforestation has been done. It was pointed out that one of the greatest difficulties to reforestation, whether by mining companies or any one else, was the prohibitive taxes levied by the state. In Europe, it is customary to tax reforestation areas merely a nominal sum during the growth of the trees, but to levy reasonable income taxes when the trees are cut. It is probable also that long-term loans by the banks at reasonable rates of interest would do much to foster timber growing.

The round-table discussion, of which this is a brief reproduction, adjourned with the recommendation that the Institute establish a reforestation section, or that a committee on this subject be appointed. It is probable that some such step will be seriously considered in the immediate future.

Tree Planters on Kingston Coal Co. Lands

A little labor places a tree; no costs but those for fire protection and taxes follow. As for fire protection, the public should be willing to pay the bill, for it is the public and not the timber owner that fires the forest, putting timber guarding on equal ground with other property protection. As for taxes, these should be levied only when the crop is taken off and a profit received.

Calls Coal Commission's Deductions on Anthracite At Variance with Facts Compiled in Report*

Conclusions Characterized as Hasty, Biased and Contradictory—Failure to Speak Firmly and Definitely When Wage Negotiations Were in Progress Caused Loss of Confidence—Comment on Herrin Massacre

BY EDWARD W. PARKER

Director, Anthracite Bureau of Information,
Philadelphia, Pa.

THE wage agreement of September, 1922, between the anthracite operators and the United Mine Workers of America, which followed the 5½ months' strike during the summer of that year, contained the following provision:

The parties unite in a recommendation to Congress that legislation be forthwith enacted creating a separate anthracite coal commission with authority to investigate and report promptly on every phase of the industry, and the parties hereby ask the President to request the enactment by Congress of the recommended legislation.

The continuance of production after Aug. 1, 1923, shall be upon such terms as the parties may agree upon in the light of the report of the commission.

The request for a separate commission to study and report upon the conditions in the anthracite industry was not granted, but that fact did not relieve the U. S. Coal Commission, which was appointed to investigate and report upon both the anthracite and the bituminous-coal industries, from the responsibility of handing down a report on conditions in the anthracite industry, in the light of which an agreement in 1923 might be negotiated. The commission was instructed to make a separate report on anthracite, and it did—not only one but several of them—but if they contain any suggestions of a concrete and workable character that will lend aid to the negotiating of wage agreements, careful study of thousands of mimeographed pages issued by the commission has failed to find them.

The commission, most unfortunately, surrounded itself with a somewhat motley assembly of communists, sociologists and social and industrial uplifters, through whose doubtless entirely well-meaning efforts the main object for which the commission was appointed—the spreading of a light upon a path toward peaceful wage negotiations—was lost sight of.

The commission expended approximately \$600,000 appropriated for it by Congress. It has been estimated that the work of furnishing the mass of detailed

E. W. Parker

information called for by the "expert advisers" to the commission cost the anthracite operators in the neighborhood of \$1,500,000, and the bituminous-coal operators not much less than \$5,000,000. And with what result? The mimeographed reports of the commission, which I have heard will occupy 8,000 pages of printed matter if Congress ever concludes to publish them, contain many valuable facts regarding the coal industry—many of them were already known, it is true, but we'll let that pass—but because of the hurried manner in which the work was done and the unfamiliarity of the commission's experts, as well as some bias on their part, the information as collected was not properly or, in many cases, intelligently digested; contradictions of a serious character are found in different reports and even in the same report, and many of the conclusions drawn, which express the opinions either of the commission or of its hired experts,

are not in accord with the facts that they themselves compiled.

It will be remembered that the representatives of the anthracite operators and the United Mine Workers met in Atlantic City in July, 1923, for the purpose of negotiating a new agreement to succeed the one that was to expire on Aug. 31, this new agreement to be arrived at "in the light of the commission's report." Under the law creating it, the commission was to hand down its report on anthracite on or before July 1, 1923. The coming of that report was eagerly looked for by the contending parties, for both sides anticipated, hopefully, that it would furnish a plan upon which they could come to an amicable understanding.

Two copies of the report were received by the operators by special messengers Saturday afternoon July 7, and a good part of that night, the next day, Sunday, and Sunday night were devoted to the study of that report in the hope that something constructively suggestive would be found. To say that they were grievously disappointed is to express it mildly. There was some consolation, however, in the fact that the other side derived no more comfort or benefit from it than did the operators, and after a brief discussion of some

*Part of address entitled "A Few Comments on the Work and Reports of the U. S. Coal Commission," delivered at the meeting of the American Institute of Mining and Metallurgical Engineers, coal and coke committee, held at New York City in February. Mr. Parker's paper will be concluded in a later issue.

of its paragraphs, the following day (Monday) the report was by common consent, figuratively speaking, consigned to the scrap heap. Instead of helping, it actually aggravated the situation.

When the first break came in the negotiations at Atlantic City and each side lay resting on its oars waiting for some move by the other, the commission injected itself into the controversy, called the negotiating committee together at the Hotel Pennsylvania, New York City, poured a little oil and persuaded the joint conference to resume its deliberations at Atlantic City. When it appeared that an agreement was not even then going to be reached, the commission boldly announced that if an agreement were not reached it "would fix the responsibility." How we all shuddered at that dire threat! Do not let it be forgotten that the anthracite operators offered to submit all matters in controversy to arbitration—even to the inclusion of the "check-off," which up to this time they had absolutely refused to concede. In spite of the fact that the operators had offered arbitration, which the leaders of the miners refused, and that public opinion desired and was entitled to guidance, and in spite of its bold declaration that it would fix the responsibility, the U. S. Coal Commission remained mute. Why?

COMMISSION SHOULD HAVE TAKEN STAND

There is a general feeling that whether it possessed authority or not, the commission should have spoken firmly and definitely at that time, and that in its failure to do so, particularly having stated that it would, the commission lost an opportunity to perform a distinct public service. The omission cost the commission much in loss of respect and confidence. It might have assumed a virtue (of authority) if it had it not.

In a later report on Labor Relations, the commission does apparently recognize that the primary cause of its appointment was the stoppage of the flow of coal from mine to consumer because of strikes. It says:

The frequency with which labor troubles have stopped production of anthracite coal, the disregard of public interest shown on occasions in the attitude of one or the other of the parties to these controversies, and the apparent impotence of the public to protect itself has created a situation that the public considers intolerable. In the search for a remedy certain citizens are advocating even so drastic a measure as nationalization of the mines while others are insisting on compulsory arbitration and outlawry of strikes. The demand for some sort of remedial public action is practically universal.

This statement was well justified by the pronouncement of President Harding on Aug. 18, 1922, when he said that but for the unorganized miners "the country is at the mercy of the United Mine Workers." It is borne out by another statement of President Harding and the commission: "Industry and the home alike must be freed from the menace of constant interruption of their coal supply." The danger is emphasized by the fact that the United Mine Workers in 1922 officially boasted: "We refused arbitration from the President of the United States notwithstanding that all the pressure of the government was back of the proposal," with the result, as further stated by the United Mine Workers, that "the greatest industrial dislocation in the history of the world" ensued.

Bearing in mind this critical situation, the General Policies Committee of Anthracite Operators submitted a statement to the Coal Commission on the strike of 1922, which closed as follows:

The strike is a legitimate weapon to drive an economic

bargain with a selfish employer, but there is no moral right, and should be no legal right, to organize strikes or lockouts in basic industries or transportation where disinterested agencies for adjustment and adjudication are available. A national combination, controlling coal production, whether it be of employers or employees, which disregards the public interests and wilfully seeks to produce a coal famine by refusing to arbitrate industrial disputes, deserves correction and regulation at the hands of government. A government which is unafraid can do no less than meet this issue. If society has a right to protect itself against abuses in the coal industry, here is occasion to act. If this major problem goes unremedied, there is no consistency in proposing remedies for minor problems.

In substance the commission found the real cause of this major difficulty was refusal of the miners to accept the operators' offers of arbitration. It attributed strikes and lockouts to "unwillingness to present controverted points to any sort of arbitration," and added, "compulsory arbitration is not only impossible but undesirable. Voluntary arbitration is desirable."

The commission did feel that something should be done to overcome "the disregard of public interest shown on occasions in the attitude of one or the other of the parties to the controversies and the apparent impotence of the public to protect itself," and it recommended that "90 days prior to the expiration of the agreement the parties should indicate which provisions they desire to have changed and should immediately confer on the proposed changes. If, within 60 days of the expiration of the agreement, they have not agreed, they should report to the President, who shall appoint a person to make public report of the facts."

SOUGHT TO GIVE PRESIDENT A FREE HAND

The commission was itself in existence while the negotiations were being conducted in 1923 and the stoppage of coal by strike was threatened and it kept silent.

The Coal Commission also recommended the following emergency power be vested in the President of the United States in time of industrial disputes:

The President of the United States should be authorized by act of Congress to declare that a national emergency exists whenever, through failure of operators and miners in the anthracite industry to agree upon the terms of employment, or for any other reason, there is a suspension of mining operations, seriously interrupting the normal supply of anthracite fuel in interstate commerce; and to take over the operation of the mines and the transportation and distribution and marketing of the product, with full power to determine the wages to be paid to mine workers, the prices at which the coal shall be sold, and, subject to court review, the compensation to be paid to land and mine owners. (July 9, 1923, pp. 4, 5.)

The objections to this recommendation and the possible injustice of it are obvious. If the operators are willing to be bound by arbitration directed by the President of the United States, and the unions refuse to be bound by that arbitration, it would seem unjust to take the mines away from the operators and then have the President arbitrate the wages. If governmental authority can fix the conditions under which the men are to work and the operators are willing to be bound by such authority, it is unjust and unnecessary to take over the operation of the mines.

The failure of the commission to exert effectually its influence in the settlement of the controversy last summer resulted eventually in passing the buck to the Governor of Pennsylvania, who effected a "settlement."

Another matter that is to be regretted in regard to the work of the U. S. Coal Commission is the fact that it steadfastly denied the requests of the operators and

the miners for open hearings in which parties to the controversy could be given an opportunity to learn what manner of information was furnished to it and upon which it based some of its conclusions. The proceedings were of the star-chamber character and no opportunity was afforded to deny statements made by witnesses or to cross-examine them. Both sides presented elaborate briefs, it is true, and they were made public, but not in such a way that the public itself, the party most concerned, was able to obtain an intelligent and comprehensive idea of the subject. The anthracite operators presented no less than eight of these briefs. They covered the following subjects:

- The Anthracite Coal Strike of 1922.
- The Anthracite Emergency of 1922-1923.
- Outlaw Strikes in the Anthracite Fields.
- Union Rules and Practices Limiting Output and Impairing Efficiency in the Anthracite Fields.
- Need for Greater Democracy in the Union.
- Competition in the Anthracite Industry.
- Summary and Recommendations as to Industrial Relations in the Anthracite Fields.
- The Union Ultimatum: The Check-Off or No Anthracite.

So far as the operators know, the United Mine Workers did not attempt to contradict any of the statements in the briefs of the anthracite operators. It certainly did not in all the numerous and lengthy documents filed by it. It is gratifying to be able to say, however, that on all major points of fact the findings of the commission sustained the statements contained in those papers.

I have said that some of the conclusions of the commission were not in accord with the facts as found and published by it. The commission states, for instance, that anthracite is a necessity and that in consequence its production is charged with a public interest.

LESS ANTHRACITE THAN BITUMINOUS USED

The use of anthracite, even for domestic purposes, is the exception rather than the rule. There is more bituminous coal used for domestic purposes in the United States than there is anthracite. In England, where the great Welsh anthracite fields are not far removed from London, anthracite is not generally used for domestic purposes. Throughout the entire world it is only in the Northeastern United States where the use of anthracite predominates. It is not a necessity of life and never has been. It is really a luxury fuel.

Secretary Hoover's commission of experts appointed to investigate the subject of community storage says emphatically that anthracite is not a public necessity; that in no community examined was it an exclusive fuel, its use varying with its price, as compared with other fuels, from 2 per cent of the total fuel used in a city like Indianapolis, to 60 per cent in a city like Buffalo. Even in the heart of New England only 42 per cent of the fuel of Worcester was anthracite.

The proof of these assertions lies in the substantial encroachments now being made by other fuels upon the anthracite supply. In New York City alone within a few months more than 400,000 tons of anthracite were displaced by oil.

Anthracite does not enjoy any particular franchise from the state and has no exclusive privileges. The only reason for suggesting that it is impressed with public interest lies apparently in its limited supply, but in view of the fact that it is not an essential of life and is used only in a limited way in a limited territory, it cannot justly be said that its production is impressed with a public interest. One of the members of the Coal Commission, Dr. George Otis Smith, has

since admitted that the commission's statement that anthracite is a necessity was an error.

The commission is, in the minds of some, equally loose in some of its other statements, among which may be included its remarks about monopoly and lack of competition in the anthracite industry.

The detailed facts as found by the commission show a total commercial production of about 72,000,000 tons (page 11, Report on Cost of Production); 140 operators produce about 98 per cent of the product (page 11, Report on Cost, etc.); 10 companies produce about 73 per cent; the larger independents produce about 16 per cent; small independents produce about 11 per cent

Herrin, the Town Where Men Were Massacred
for Mining Coal

The illustration shows the county court house and some other buildings. Of the population in Williamson County, of which Herrin is the county seat, 54,052 people at the last census, out of 61,092 were native-born and only 3.2 were illiterate.

(page 10, Report on Cost, etc.); culm-bank operators produce about 5 per cent (page 12, Report on Cost, etc.).

The largest company produces about 15 per cent and it takes four or more companies to make up a total output of 50 per cent. Therefore, the industry does not show any greater centralization of production or any greater domination by any one concern than often exists in many industries. Whatever may have been the history of the industry in the past, as shown by court decisions, there is today no combination or arrangement, direct or indirect, restraining competition either as to price, production, distribution or allotment of territory. The commission could not have had any evidence before it to that effect except where the industry is co-operating with public officials in the public interest. If its numerous statements as to monopoly are by their implications or intendment contrary to this statement, then they are without foundation.

Various statements of the commission, however, convince us that, in spite of such general language, it intended to find that there was monopoly only in the sense that the supply was limited, with the result that when shortages are produced by strikes, there is always a so-called "sellers' market." The commission states:

There is and can be no such free competition because the supply is limited and controlled . . . The usual under-supply of anthracite and the frequently recurring extreme shortages together make unnecessary any overt act to control the market; even with a potential monopoly of production, it is not necessary that there should be a combination

in restraint of trade in the legal sense to explain present price levels.

The commission expressly points out that "if there be a monopoly in effect it is not in the sense of pooling cost and profit among the railroad companies but in the sense that practically uniform prices have been charged by the railroad group." It states that its studies have brought "to light no evidence that economic combination takes the form of concerted partition of territory either among the larger companies or between the railroad and the independent companies. . . . If there is any well-founded suggestion of concerted action, it is shown in the small range of circular prices, the extremes in prices of company coal of domestic sizes being only 35c. although all this coal could be sold at the higher circular price and probably much nearer the price level of the independent coal. Doubtless both business sense and regard for public opinion have led these strong companies to acquiesce in the noticeable differential between their own prices and the higher prices of the independents."

From these statements of the commission it may be concluded that conditions are such that no overt act or combination in any legal sense is necessary "to explain present price levels," and if there is "any well-founded suggestion of concerted action," it is only due to the fact that company prices show small differentials, and these companies, out of recognition of public interests, charge less than they are able to get for their coal and thereby permit a differential to exist between their prices and the higher prices of the independents.

PRICE DIFFERENTIAL EVIDENCE OF COMPETITION

We submit that the differential in prices charged by the companies who produce at a large profit as compared with the companies who produce at a low profit, as well as the differential between these companies and the independents, is evidence of competition, and that even if the prices were more nearly the same level it would be no evidence of combination, since prices of standard commodities, just as in the case of wheat, cotton, copper and like grades of bituminous coal, naturally tend toward the same level regardless of the cost of production. In a competitive market, which is compulsory under our laws, these prices gravitate toward the price

of the highest-cost company whose production is necessary to meet public requirements.

In addition to forbearance in the public interests on the part of the large-profit producers to keep down their prices, the commission also found that the operators had co-operated with the public authorities during the crisis of 1922 in an effort to effect equitable distribution of the short supply at reasonable prices. The commission says:

Realizing the hardships that a runaway market would inflict upon those least able to pay high prices, the Pennsylvania Fuel Commission, with the co-operation of all but a few operators, mostly irresponsible persons attracted to the business by the existing shortage, fixed a scale of "fair prices." According to the Pennsylvania Fuel Commission the coal mined by the "railroad companies" and certain independents—over 77 per cent of the total—was sold at \$8.50 or less, these circular prices being adhered to at this time of acute shortage just as in a time of abundance. Unquestionably, these large producers might have obtained from the retailers of anthracite during the past winter much higher prices. This commission desires to pay public tribute to the restraint and good judgment displayed by the responsible shippers of anthracite during that trying period.

The record shows that there is no combination in the anthracite industry which can be called a monopoly or which in any way seeks, except when acting at the direction of a public agency, to regulate distribution, production, or prices, or in any way to restrain competition.

STRONGLY FINANCED COMPANIES BENEFIT PUBLIC

The commission admits that "real benefits have flowed to the public from strongly financed companies, . . . that the anthracite mines have conserved the country's coal resources," by steadily increasing the percentage of recovery, and that they have economized in the capital employed and improved the economic condition of the mine workers, and while, as stated above, it pays tribute to the restraint and good judgment displayed by these companies during the trying period following the strike of 1922, it goes on to say that "the ability to stabilize prices that was used last winter by the larger companies to benefit the public contains also the inherent possibility of real danger." It has since developed that there was more than a possibility of real danger in that action of the anthracite operators, but it was not the kind of danger the commission had in mind. It developed when these same companies made their reports to the State of Pennsylvania on their receipts for the year that were subject to the much-discussed tonnage tax. These reports were rejected by the tax authorities of the state on the ground that the companies sold their product at less than the market warranted.

The commission finds that "in the anthracite region the union has won its fight for collective bargaining and now exercises a practical monopoly," and it suggested that the operators should unite into a stronger and more central organization in order to meet this situation. It found that because of the absence of such organization,

Each operator must depend on his own unaided power and ability in dealing with the union. A disproportion in relative bargaining effectiveness results. This is in large degree responsible for the fact that the union has been able within the agreement period successfully to bring pressure on individual operators resulting in a practical and irritating modification of the terms of the agreement. In case of complaint by the operator over this pressure the weight of the operator's objection is that of a single company. So long as this disproportion in bargaining effectiveness exists,

Law Is Defended When Union Is Not Involved

Prompt action in the Ku-Klux trouble defended the majesty of the law, but when in 1922 the United Mine Workers of America opposed itself to law and order and nineteen men were murdered in cold blood the authorities hesitated, holding that there was no occasion to call out the National Guard for the defense of those who were willing to work, or to maintain order thereafter.

©International

the process of attrition of the agreement will be likely to continue. Moreover, another course of great strikes is likely to ensue corresponding to those between 1900 and 1912. This time, however, it will probably be the operators instead of the union who will be appealing to the public for fair play.

Of course, in view of the anti-trust laws and the recent activities of the Federal Trade Commission and the Department of Justice, there might be some question as to the ability of the anthracite operators to carry out this suggestion, but little things like that have not worried the commission. We need not deceive ourselves, nor attempt to disguise the fact that the United Mine Workers has a throttle hold on the anthracite industry and on the anthracite-consuming public. The so-called certificate law of Pennsylvania makes this hold, in the vernacular, "a lead pipe cinch," and the Governor of Pennsylvania says it is a good law.

The act of Congress creating the U. S. Coal Commission provided that the commission should investigate every phase of the coal-mining industry, both anthracite and bituminous, but the commission evidently decided that the most potent influence affecting the supply of both hard and soft coal was not a subject to be investigated—namely, the United Mine Workers of America. True, the commission held some star-chamber interviews with the leaders of that organization, and it permitted the submission of briefs, which, with those of the operators, it designated as swashbuckling literature; but while it "poked through knotholes and pried through cracks" to learn every detail of the operators' business from the profits on investments to the care of children in the mine workers' families, and the sani-

tary conditions of dwellings and communities, it never attempted to get any real facts as to the affairs and activities of the mine workers' Union.

Its comments on the Herrin massacre are perhaps the most remarkable statement contained in the many pages of its report. It cites what it states are certain facts which it says it believes will give a clear understanding of the real situation, but out of its high regard for the president of the United Mine Workers, or for fear of offending his sensitive nature, it carefully avoids quoting the telegram from him which, according to common belief, precipitated the murders. But it does say that when "the promoter of the Southern Illinois Coal Co. started to operate his mine in defiance of the union he was inviting mob violence and was flirting with death; he knew it and prepared to meet it. . . . *He challenged the supremacy of the union.*" In other words, these murdered men got what was coming to them, because they defied the supremacy not of the laws of the land but of the United Mine Workers. The commission found that the tragedy might have been prevented, but it does not say how—and it concludes its discussion of this affair thus:

Clothed with all the charitable *excuses* [excuses, mind you] above set forth, these furnish no justification for the brazen audacity with which subordinate officials and members of the United Mine Workers defended the crime and the criminals. That they were espousing the cause and defending the law breakers is further shown to the commission by the fact that they have since bought the mine where the tragedy occurred and have paid therefor \$729,000.

I believe that this is the most remarkable statement that ever issued from an investigating body.

The Miner's Torch

"A Greased Mouth Cannot Say No"

APPROXIMATELY one-third of the front page of every daily paper these days is devoted to dispatches covering some phase of the Teapot Dome oil scandal investigation. If you happen to sit down beside a stranger reading a newspaper he is more than apt to open the conversation by remarking that politicians have always been classed as dishonest, but now we will have to coin a new word if we want to give them full justice, or something to that effect.

Far be it from me to pose as a defender of grafting politicians (I hope the ones who have been "oiled" will never be able to stand on their feet again), but it occurs to me that if we assume that politicians are the only ones who should benefit by the disclosures now being made at Washington we must be very ignorant of conditions in other lines of endeavor. Ministers tell us that their sermons do not bring hoped for results because so many of their hearers assume that the sermon is directed at a neighbor—Washington is releasing some pretty convincing sermons these days.

Getting personal, here are a few instances of graft recalled from my experience while employed in the coal industry.

A company operating a mine adjoining the one where I happened to be employed as mine superintendent obtained more than its allotment of empty cars from

the railroad during a period of car shortage by furnishing the station agent and some of the train conductors shirts, hats and other articles of wearing apparel. I have heard of the same results being accomplished by substituting whiskey for wearing apparel (that happened back in the days before prohibition had become the law of the land) but I only know of this by hearsay.

A superintendent of my acquaintance obtained a considerable amount of stock in a fake insurance company for no other consideration than the use of his name to lead on suckers from his list of employees. The insurance company was thrown into bankruptcy several years later and all of the investors who retained their stock lost every penny invested. The superintendent had disposed of his stock before that happened.

A mine foreman working for me "sold" the desirable working places in his mine over a period of more than a year before I could satisfy myself as to the truth of reports that were brought to me by men who were entitled to the places thus disposed of.

A commissary manager at one of the camps where I was employed practically furnished his home with articles given to him by drummers who were able to profit by his recommendations.

I have been told that an engineer employed by me augmented his income by favoring miners with yardage measurements but I can only repeat this as hearsay.

Probably there is less graft in business today than there was twenty-five years ago, but there is graft a plenty even now; if we are to profit by the discomfort of the politicians who have recently been exposed in Washington it were well not to emphasize too strongly the word politician.

Where the Power in a Coal Mine Is Used or Wasted

Each Mine Has Its Own Power Problem—Thus One Small Mine Uses Half Its Power for Pumping Yet Only Five per Cent of the Whole Load Is Spent in That Way at the Average Illinois Mine

By A. J. HOSKIN

University of Illinois, Urbana, Ill.

WHILE contemplating the more serious difficulties that labor and the market present, a coal operator is likely to overlook the importance of his power problem and fail to note the proportionate parts of his power bill which the several operating activities at the mines compel him to expend. Though it is universally true that the labor cost in coal mining exceeds the sum of all other operating costs, and that supplies stand in the second place in mining expenditures, it is well to remember that the cost of power to run the machinery takes third place and it appears to be slowly increasing. With the probable substitution of mechanical loaders for hand shovelers there will be an increased demand for power. Whether this added expense will be fully compensated by the decreased cost of labor consequent on the use of more power remains to be shown.

A close analysis of practical conditions in several Illinois mines shows that their power requirements vary greatly. Despite arguments to the contrary the study fully corroborates the statement that the power demand for every coal mine is a problem unto itself. Actual figures from fifty representative Illinois shaft mines substantiate this claim.

To permit reasonable comparisons between power consumptions at different mines, it was necessary at first to classify such consumptions. I therefore chose to separate the total power consumption into six classes; namely hoisting, ventilation, pumping, mining, haulage and miscellaneous. The last item included illumination, heating of buildings and wash-house water, driving shop machinery, surface pumping, and all tippie equipment, but it did not include coal-washing which is, as yet, practiced at few mines.

Every practical coal-mining operator or engineer will promptly express doubt as to the possibility of accurately apportioning the total power consumption of every mine to these six headings. The argument is

well taken. I admit that in certain cases the facts were not readily ascertained. Nevertheless I believe my findings were sufficiently accurate to afford dependable comparisons.

Among the fifty representative mines selected, the average daily tonnages ranged from a minimum of 650 to a maximum of 5,200. Ten of the mines produced less than 2,000 tons each; the next nine mines produced less than 2,500 tons each; the following nine had average daily outputs below 3,000 tons; then there were ten mines shipping nearly 4,000 tons; the last twelve had daily outputs between 4,000 and 5,200 tons. The average production of the fifty mines was 2,828 tons.

All the mines included in the survey are entered by shafts. Their hoisting depth ranges from 101 ft. to 650 ft., and the average depth is 325 ft. The seams of coal vary in thickness from 3 ft. 6 in. to 10 ft., the average being a little more than 7 ft. Most of the mines are operated by mixed power, that is, they use both steam and electric power. However, two of the mines utilize steam power exclusively for hoisting, ventilating and pumping, the mining being manual and the haulage by mules. On the other hand, five of the mines are wholly electrified.

Without explaining the methods of determining the distribution of the total power consumption at each mine, I cite a few interesting figures. The reader must bear in mind that each item is a percentage of the whole power consumption at the particular mine. Curiously the most consistent item was miscellaneous which at the majority of the mines ranged close to 10 per cent of the total consumption. In fact, the average for the fifty mines was 10.5 per cent. In the other classifications there was much variation.

HOISTS USE 1.4 TO 50.8 PER CENT OF POWER

The consumption of power for hoisting purposes varied between 1.4 per cent and 50.8 per cent of the total demands for power. The percentage was not a direct function of the depth of the mine nor of the production. The mine having the greatest proportional hoisting consumption averaged only 2,000 tons per day, whereas mines that produced around 4,000 tons used less than 20 per cent of the total power for this purpose. Mines whose depths were between 200 ft. and 300 ft. had an average hoisting percentage of 15.9 while those between 300 ft. and 400 ft. had a corresponding average percentage of 14.2. But these items must not be made the grounds for stating rules because many idiosyncrasies tend to wholly discredit only generalities. The weighted average demand for hoisting was 17.2 per cent.

The average demand for ventilating was 22.2 per cent but it varied from 2.2 per cent to 61.9 per cent. It is noteworthy that these extremes occurred in mines having small productions. Considerable variance appeared in the ventilation demands of mines having equal outputs regardless of the size of the output. Thus one of

Power Plant at No. 4 Mine, Superior Coal Co.

The extreme left hand end of the building houses the main hoisting engine. The remainder of the building encloses the boiler and generator rooms.

the 3,000-ton mines consumed 38.9 per cent of its total power for operating the fans whereas another 3,000-ton mine used only 17.3 per cent. The fans of one 4,000-ton mine consumed 12.7 per cent whereas those of another mine of the same production consumed 26.4 per cent. One mine with a daily output of only 1,600 tons showed this same percentage for ventilation.

The smallest mine, from a production standpoint, had the greatest proportional demand for pumping, namely, 52.2 per cent. However, this was abnormal and not approached in another instance. The weighted average for pumping including some dry mines, was 5.0 per cent. No direct ratio or relationship could be discerned between production and pumping demands.

The classification under the term mining means the undercutting of the coal. From a power demand of nothing in mines where all coal was cut by hand, the percentage varied to a maximum of 45.7, this being in a mine producing 2,200 tons per working day. The true or weighted average demand was 22.1 per cent. Again the scale of production bore no consistent relation to the power requirements. The smallest mine had a percentage of 22.0 and the biggest a percentage of 22.8—paradoxically close to each other and to the general average. This item for one 2,000-ton mine was 2.5 and for another mine of same output it was 29.6. For one 4,000-ton mine it was 13.2 and for another it was 43.8.

Haulage had an average percentage of 23.0. Disregarding animals as power units, the percentage range was from nothing in mule mines up to 51.0. Still again the proportion was not a direct function of production. The weighted average for mines whose productions were below 2,000 tons per day was 31.2. The corresponding figure for the twelve largest mines was 30.4. These close figures are somewhat conclusive until we note that, for the mines in the lesser class, this percentage fluctuated from 6.2 to 34.9, and in the largest class the fluctuation was similarly between 6.2 and 41.1.

If any general deduction from the foregoing discussion is possible, it is that, in general, ventilation, mining and haulage consume approximately equivalent proportions of power, and that each is approximately equal to the sum of the hoisting and pumping requirements.

It must be borne in mind that I am discussing power requirements by percentages and not by magnitudes. One mine's 24-per cent demand for its hoisting might be less in horsepower-hours than that of another mine whose demand was say 17 per cent. At one mine whose mining demand stood at 34 per cent, the actual power consumption may have been less than that at another mine whose percentage was say 20. In other words, the figures permit no comparison of quantitative consumption. They prove conclusively, however, that it is impossible to fix any dependable relationship between the several consumptions of power in coal-mining operations.

Modern Coal Mine Power Plant

From this plant power is distributed to several nearby mines; there it is used both outside and inside. Large power cables hanging in boreholes supply the cutting and haulage machinery.

The weighted average percentages of total power consumptions at fifty representative Illinois shaft coal mines are as in Table I.

Table I—Percentage Consumption of Power at Fifty Illinois Shaft Mines

Hoisting	17.2
Ventilation	22.2
Pumping	5.0
Mining	22.1
Haulage	23.0
Miscellaneous	10.5
Total	100.0

This distribution, however, cannot be safely applied to Illinois coal mines in general. As a matter of fact, there is not one mine in the list for which this distribution is even approximately applicable. The distribution of total power is a distinct problem for every mine.

Progress Made in Mine Communication

In the course of experiments designed to perfect methods for the establishment of wireless communication between persons entombed in mine disasters and rescue workers on the surface, conducted by the Department of the Interior at the experimental coal mine of the Bureau of Mines, near Pittsburgh, Pa., signals have been transmitted obliquely through a distance of 800 ft. of rock by the use of the T.P.S., or ground conduction system, developed by the Signal Corps of the Army. Signals were also transmitted with little difficulty, by using compressed air piping, car rails, and other similar conductors. The intervention of such poor conductors as water, coal and mud, and the substitution of wooden for steel rails, did not interfere with the transmission of signals.

The T.P.S. method of ground telegraphy is a means of communication which requires no wire connection between the sending and receiving stations; but it is different from radio telegraphy in that the transfer of electrical energy from the transmitting to receiving apparatus takes place mainly by conduction, and to a much less extent, induction through the ground, instead of through the air as with radio. This method of signaling is for telegraphy only and cannot be used for voice or speech transmission.

Unless the Public Acts, Taxes Will Not Be Reduced

Surtaxes Higher in America Than Anywhere—Acquired Fortunes Favored by Surtaxes as Against Newcomers—No One Can Reasonably Assert War Was Fostered for Private Gain—Excessive Taxes Cripple Everybody

PEOPLE of small means are subject under the existing law to a far smaller rate of income taxation in this country than in any country of Europe," says Otto H. Kahn in a little booklet entitled "Why I Favor the Mellon Tax Plan." "On the other hand," he adds, "considering only surtaxes, people of wealth in this country are subject to higher rates than in any country of Europe, not to mention the fact that 'capital profits' are not liable to income taxation at all in England and in other European countries, whereas our taxation applies to all kinds of income or profits.

"That we are able in this country to meet our budgetary requirements while placing but a light burden of income taxation on those of small means and practically none at all on families with incomes less than \$4,000 a year, is a fortunate and desirable situation.

"But surely there must be some socially and economically sound reason for the fact that not a single European country has thought it wise to raise its surtaxes to the level of ours, notwithstanding the fact that they have greater need than we to find sources from which to draw revenue for the Government."

Mr. Kahn adds that "our highest surtax is 50 per cent, whereas in England, 30 per cent is its maximum figure. England's normal income tax rate, that is, the rate payable by the man with a small or moderate income, is 22½ per cent, which is approximately three to six times as high as our tax rate on small or moderate incomes. Consequently, taking the normal and surtax rate together, the comparison is less striking, being 58 per cent maximum with us as against 52½ per cent maximum in England."

PRESENT SYSTEM FAVORS ACQUIRING FORTUNES

Speaking about the effect of the surtax on the acquirement of wealth by the budding capitalist, Mr. Kahn remarks "The road to conspicuous material success is blocked to the newcomer by the barricade of the surtaxes. Surprising though it will sound to the advocates of extreme taxation, it is a fact that by these very imposts, existing wealth is fortified against would-be competitors, and the handicap against him who starts with little is made greater.

"Manifestly, when a man sets out with small capital the possibility of his accumulating large resources is greatly diminished by a law which compels him to turn over to the Government in cash the larger part of that which conspicuous ability, inventive genius, daring enterprise or good fortune may enable him to earn."

Combating the idea that the high surtax is justifiable because it merely recovers pelf from those who profited during a war which they fostered for their own gain, Mr. Kahn says that no one could accuse President Wilson, who declared war, of seeking any but his own counsel, and certainly not of truckling to Wall Street and the moneyed interests; that the period prior to the war was ideal for the making of money, for the Allies "had to buy large and increasing quantities of some of the products of our soil and industries, practically regardless of profit; that the war promised to Wall

Street only control of prices, differential war taxes on the well-to-do and rich, and that the war injured capital by draining the market by its bond issues of all available funds.

He adds that only 4 per cent of our population was conscripted and less than one per cent saw actual fighting, whereas the incomes of the wealthy were conscripted to an extent rising to nearly 80 per cent. The conscription fell more heavily on the well-to-do, for the children of the rich were not able to show that they "were needed at home to support dependents or to man essential war industries" and so were not exempt from the draft. Mr. Kahn adds, "The draft regulations discriminated, not, as was too often the case in former wars, in favor of the son of the rich man but in favor of the son of the poor woman."

HOW HIGH TAXES INJURE WORKMAN AND INDUSTRY

He argues that the surtax percolates downward and affects the man who does not have to pay it directly; that, as taxes must be paid in cash and not in book assets, bills receivable or inventories, they unduly unsettle business and make for instability of industry, and that the money taken from industry and given to the Government is of less potential value than when held in private hands. Mr. Kahn adds, "Even if capital did not have the refuge of tax-exempt securities, its dynamics would be bound to deteriorate under the influence of extreme surtaxes, and some of it would sullenly resign itself to a much lessened return rather than venture into a game governed by the rule that the player takes all the risk of possible loss, all the burden of work and worry, but gets only a minor share of possible profits.

"You can take a horse to water, but you cannot make him drink. You can starve capital, but you cannot make it take the risk, worry and effort of new enterprise, unless you hold out the eventuality of adequate reward.

Mr. Kahn declares that capital did not for some time after the war was over take refuge in tax-exempt securities. Convinced at last that the taxes were not justified but were the outcome of class privilege, political considerations and sectional animosity "capital took such steps as were lawfully open to it to escape from what it regarded as unwarrantably and unnecessarily burdensome taxation." This statement is clearly borne out by the following figures of surtaxes collected by the Government on incomes of \$300,000 or above:

1917.....	\$201,937,975	1920.....	\$134,709,112
1918.....	220,218,131	1921.....	84,797,344
1919.....	243,601,410		

The Citizens' Committee in support of the Mellon Tax Reduction Proposal, Hotel Biltmore, New York City, which publishes this brochure, announces a National Tax Reduction Week beginning Monday, April 7, and urges that representative community and industrial associations flood Washington with letters and telegrams during that week. Unless active steps are taken to turn the tide against self-seeking politicians, taxes will not be reduced.

News Of the Industry

Guaranteed Contract Urged to Restore Confidence in Coal Industry

Co-operative Plan Proposed to Insure Delivery in Case of District Strike—
Three-Year Pact with Customers Would Enable Union Producer
to Offer Inducements to Overcome Price Disadvantage

By PAUL WOOTON
Washington Correspondent of *Coal Age*

With the approach of the time when most coal contracts expire, there is a revival of the discussion of the advantages which could be obtained from new types of contract. The public utilities long have been insisting on more binding contracts. With consumers generally the present form of contract is in disrepute. Under existing conditions many believe contracts could be put on a basis which would be more satisfactory to the purchaser of coal and which would be of material benefit to at least the union operator.

Just at this time the ideal condition for the union operator would be to negotiate three-year contracts with his customers. Many believe there are contractual inducements which he can make which will tend to overcome the disadvantage he is under in the matter of price. If consumers could be insured constancy of supply, any price differential likely to exist between union and non-union coal, in many instances, would not be the controlling factor in the purchase.

Pledge Would Assure Buyer

If the union producer were to pledge himself to ship as long as he has any coal, sacrificing his own spot tonnage if need be, it obviously would be a bid more likely to be accepted than were it offered under the conditions of present contracts, which so frequently are unsatisfactory to the purchaser during periods of car shortage or strikes. If, in addition to the guarantee to ship coal as long as the producer has any coal not covered by other contracts, provision were made for an arbiter in case of dispute, it would have further appeal.

The present discussion of forms of contract, however, which really had its beginning during Mr. Wadleigh's administration as Federal Fuel Distributor, goes much further than the removal of the free coal provision. Some suggest that producers would be well advised at this time to interest consumers in sliding-scale contracts—the variable feature, applying to deliveries as well as to prices. Special rates would be offered during the off months so as to equalize the annual output.

In this way the operator could plan to have his surplus of spot coal entirely free from contract obligations at a time when transportation troubles are most likely.

There is a well defined feeling on the production side of coal that something should be done to re-establish the reputation of the coal contract. The suggestion has been made that meetings could be arranged by districts between operators and their customers at which agreement could be reached as to types of contracts. For instance, if the operators in one district were to invite representatives of the National Association of Purchasing Agents, of the wholesalers and of the retailers with whom they deal, and should they be able to negotiate certain standard forms of contract, it would do much to bring about mutual confidence and respect.

The suggestions being made go even further. In order to insure further the constancy of supply under contracts the thought is advanced that the producers in a given field could underwrite each other's contractual obligations. Twenty-five operators, for instance, might agree to fill collectively the contract of one of their number were his production to be interrupted. The collective action might go even further and arrangements be made between districts, whereby under certain conditions other districts would attempt to fill the contracts held by operators in the event of a district strike.

Miners Ratify

Naturally the miners ratified the wage agreement which the international officers of the United Mine Workers signed with the operators of the Central Competitive Field at Jacksonville, as foreshadowed in *Coal Age* last week. The official rank and file count of miners voting in the referendum was 164,858 to 26,253. Half the opposition, or exactly 13,032 votes, was cast in Illinois, where the rebel element in the United Mine Workers is strongest.

Scale Renewed for 3 Years In Central Pennsylvania

Representatives of the operators and union miners of the central Pennsylvania bituminous coal field signed an agreement at Philadelphia March 29 continuing the present wage scale for three years.

A modified set of demands was presented by the miners March 27 withdrawing the abolition of the "penalty clause," providing for suspension for the mining of "dirty" coal. The modified demands were presented at a meeting of subcommittees of miners and operators appointed to discuss the differences that had arisen in the negotiations and the breach was patched up.

To explain this scheme, southern Illinois is used as an example. Operators in that district are anxious to expand their market in the Northwest. Their chances would be greater were their salesmen in a position to make some such statement as this to the Northwestern consumer: "This contract will be signed by my company, which obligates itself to sell no spot coal until the contract is filled. Moreover, it is underwritten by twenty-five other operators producing similar coal, who collectively will make up this obligation should my company fail. In the event that southern Illinois should be tied up in a strike, we have an arrangement whereby operators in Colorado, Utah and Wyoming will undertake to supply the coal called for by this contract."

If any step toward co-operative marketing is not practicable at this time, the suggestion is made that co-operative advertising at least could be attempted. The success of the anthracite operators' coal economy shows points the way for similar action on the part of bituminous associations. The Illinois associations, for instance, by such means could call the attention of the Northwest to the advantage of the use of bituminous coal. If they were to set up standards of purity and sizing, that fact could be advertised in a market where the use of Illinois coal could be increased greatly. In that connection, attention is called to the fact that it was careful preparation as much as it was good coal which built up the trade value of the name "Pocahontas."

It is a new era in the coal business. Perhaps never before has such an opportunity existed for the exercise of ingenuity and initiative. Progress, however, is thought to lay more along the line of joint action by the operators than any other way.

Blast in West Virginia Mine Kills 26 Miners

An explosion in No. 2 mine of the Yukon-Pocahontas Coal Co., at Yukon, McDowell County, W. Va., early in the morning of March 28, caused the death of twenty-six miners. Fifteen bodies were recovered the same day by volunteer rescuers. A U. S. Bureau of Mines rescue car at Nemours, near Bluefield, was rushed to Yukon as soon as news of the explosion was received. R. M. Lambie, chief of the State Department of Mines, also left Welch immediately for the scene of the disaster.

Yukon is in an isolated section, without telephone service, and details of the catastrophe have been meager. Only six miners were rescued, but a number of others, who were late in arriving for work, escaped injury.

The presence of mind of T. J. Dawson, who became superintendent of the Yukon-Pocahontas Coal Co. at Yukon, W. Va., three weeks ago, probably saved the lives of 125 miners in No. 1 mine when the explosion in No. 2 mine occurred. When the blast came Superintendent Dawson rushed into No. 1 to warn the men there. Some of these workers were injured when they were knocked down by the force of the explosion.

Believe Head Lamps the Cause

Officials of the company and mine inspectors who have been in the mine since the blast believe the explosion was caused by the head lamps of three miners who took a short cut through an abandoned working to their places of work.

The mines of the Yukon-Pocahontas Coal Co. at Yukon, W. Va., are exceptionally dry. Describing No. 1 mine in *Coal Age*, June 1, 1922, A. F. Brosky, who made a visit to the mine, says that it had never had a pump underground and had never needed one, so dry were the workings. In the winter of 1917 seventeen men were killed at this mine in an explosion. In June, July and August the mine was sprinkled once a week and during the remaining nine months the roads were wetted down daily.

For this sprinkling, in which the whole mine participated, a 500-gallon water car was used. A 300,000-gallon tank standing 300 ft. above the coal was used as water supply and a 12,000-gallon tank at a much lower level was fed by gravity from the overflow of the larger tank. A 3-in. water line ran down the main entry for a distance of 7,000 ft. Four taps on this line at regular intervals provided for the filling of the water car, which was pulled along the roadways by an electric locomotive.

As far as possible doors were eliminated, and the machinemen carried safety lamps and were instructed to examine the mine face for gas before taking the machine beyond the room neck. Permissible powder exploded by blasting machines was used exclusively for shooting. Open lights were permitted, but the mine was examined twice daily prior to the entry of the day and night shifts.

E. S. Brooks

Mr. Brooks, whose death at his home at Rock Springs, on March 17, was recorded in *Coal Age* last week, was well known as a coal operator and mining man throughout the Central Western and Pacific states, having entered the service of the coal department of the Union Pacific Ry. in 1880, previously serving the railway company as a locomotive fireman. His first coal mining work related to the prospecting of the Gunnison County, Colorado, anthracite fields, thereafter serving in various capacities, including mine clerk, salesman, etc. He was appointed superintendent of the railroad company's Hanna (Wyo.) mines in 1894, and became vice-president and general manager of the coal company in 1920.

Bill Limits Trade Commission To Probes Authorized by Law

The Independent Office Appropriation bill, presented to the House at Washington March 27, specifies that none of the funds provided may be used by the Federal Trade Commission for investigations directed by the President or either house of Congress except those authorized by law. The adoption of this provision will make it necessary for each resolution of Congress directing an investigation by the Federal Trade Commission to authorize an appropriation sufficient to cover the expense of the investigation if it is one not relating strictly to a violation of the anti-trust laws.

The commission estimates that \$315,000 will be required during 1925 for this class of work. The Appropriations Committee, adopting the above mentioned limitation, allowed \$63,440 to provide for the normal growth of the work of the commission, the salary of the secretary of the commission being also included in this sum.

The work which the commission has this year had to do, and over which it has no control so far as the initiation of the work is concerned, has been so great that it has been slipping back, until at the present time it is about three hundred cases behind on its docket. That practically amounts to a denial of justice on the part of those who are seeking protection, Commissioner Huston Thompson told the Appropriations Committee when explaining the situation.

Union Signs Open-Shop Pact With Ky.-Tenn. Association

The open-shop four-year agreement which the union has officially signed with the Kentucky-Tennessee Coal Operators' Association is getting broad circulation at the hands of non-union operators. The new agreement now in effect in that region of union weakness runs to April 1, 1928, and contains some provisions interesting to those who struggle with labor in solidly unionized territory.

Mining rates are reduced in the region to a point 20c. a ton below the rates in effect from 1920 to 1922. Day rates for several classes of labor follow: Machine runners, \$5.40; blacksmiths and motormen, \$5; boss drivers, head trackmen, head timbermen and engineers, \$4.84; machine helpers, couplers, track helpers, wiremen and pipemen, pump men and timbermen's helpers, \$4.44; outside laborers, unclassified, \$3.72; yard couplers, \$3.64. "Inexperienced loaders" (a term unknown in union fields) are paid \$3.80 until they learn their trade.

There is no check-off except a deduction of \$1 per pay from each man's wages to be used to defray expenses of an arbitration system which the agreement sets up. The arbitration board comprises five men—two operators, one from each side of the state line, two miners of similar geographical representation and a chairman called an "umpire," to be chosen by the four. This board is to handle all cases under the agreement which cannot be adjusted by the mine committee and by direct dealing with company officials.

To Eliminate Small Abuses

There are clauses in the contract aimed at some of the most flagrant small abuses practiced generally in union fields. For instance the number of official holidays is distinctly limited and no miner may quit work to attend a funeral unless the deceased is a member of his family or an employee in the mine in which he works. Any miner who lays off to attend a funeral and doesn't attend is to pay a fine of \$2.50 to the family of the deceased.

The system of penalties under the contract applies to the companies too. In case a company shuts down a mine while some contract grievance is being threshed out it is required to pay the whole working force \$2 a day per man.

The open-shop clause reads as follows: "It is distinctly understood and agreed that men shall not be discriminated against on account of membership or non-membership in any organization nor shall any member of any organization interfere with or discriminate against those who are not members, nor shall men who are not members interfere with or discriminate against those who are."

This agreement was signed by the Kentucky-Tennessee Coal Operators Association, M. I. Roach, president, and T. J. White, secretary, and by the United Mine Workers of America, William Turnblazer, district president, and E. L. Reed, district secretary, and by the miners' district scale committee.

Hearing on New Mine-Rating Scheme To Be Held at Washington, April 23

An important hearing in the matter of the rules governing the ratings of bituminous-coal mines has been announced by the Interstate Commerce Commission to take place April 23 in Washington before Commissioner Aitchison. At that time consideration will be given the suggestions of the Harding Coal Commission in connection with car distribution. In announcing the hearing, a statement was given out by the Interstate Commerce Commission, in part as follows:

"On June 17, 1922, the commission instituted a general investigation, *In Re Rules Governing Ratings of Coal Mines Other Than Anthracite and the Distribution of Cars to such Mines*, under Docket No. 13,896. Extensive hearings were held in this matter during the summer and fall of 1922.

"An agreement was reached whereby the carriers would undertake to rate the mines through a mine-rating or inspection bureau, the members of which should be exclusively in the employ of the railway company. The principal factors used in determining the mine ratings were likewise agreed to. These factors included: (1) Physical conditions, (2) past performance, (3) labor supply, and (4) other factors that may affect the production and shipment of coal.

"The commission informally approved a fair trial of the code proposed as a result of the agreement reached after the conferences. The carriers accordingly promulgated new mine-rating and car-distribution rules, effective as of March 1, 1923, which have been maintained since that time.

Helping Off-Season Delivery

"To encourage the off-season delivery and storage of bituminous coal, the U. S. Coal Commission in its report dated Sept. 20, 1923, recommended that this commission allow the commercial ability to sell coal the year round to be the controlling influence in the distribution of railroad cars in months of transportation shortage. The principle suggested is not the controlling element in the distribution rules now in effect.

"The suggestion has been made to the commission that the principle embodied in the Coal Commission's report and embodied in the proposed code of rules attached would be legal and serviceable. The parties are invited to develop this phase of the case upon the record."

The proposed code embodying the rules recommended by the Coal Commission follows:

"(1) Whenever the supply of coal cars is inadequate to fill all orders of all mines within the limit of their physical capacity, distribution of such cars to mines shall be made upon the basis of mine ratings determined as herein-after set forth.

"(2) Mine ratings used as the basis of coal-car distribution shall be fixed

as a combination of two factors—physical capacity and commercial capacity—giving equal weight to each.

"(3) Physical capacity of mines shall be determined in accord with present methods, and expressed in terms of the number of equivalent 50-ton cars per working day. For the purpose of combining physical capacity and commercial capacity to fix mine ratings, the physical capacity shall be deemed to represent 100 per cent in terms of percentage, and that figure used in the manner set forth below.

Figuring Commercial Capacity

"(4) Commercial capacity shall be arrived at by:

"(a) Determine the actual number of equivalent 50-ton cars loaded and shipped per calendar day, not including Sundays, during the last period of not less than two months during which the number of available cars was in excess of the number ordered by all mines within the limit of their physical capacity. If the last such period of car surplus exceeds six calendar months, only the last six months of the period shall be used in determining the average. Full consecutive days in excess of one full day lost by a mine by reason of accident, strikes or railroad failure during the period used, shall be deducted in arriving at the average, when the mine throughout the calendar month in which the failure occurred loaded and shipped its full physical capacity rating on every working day that cars were furnished and the mine was not prevented from loading by accident or strike, but if a mine failed to load and ship on all days when it was not prevented by reasons enumerated, the number of days on which it failed shall be subtracted from the number of full consecutive days in excess of one full day lost by reasons enumerated, and allowance made for the remainder only.

"(b) The commercial capacity in average cars per working day determined as prescribed in sub-paragraph (a) shall be compared with the average physical capacity, in cars, for the same number of days and period of time, to determine percentage ratio of commercial capacity to physical capacity during the surplus period used.

"(5) To 100 per cent representing factor of physical capacity, add the percentage arrived at under paragraph 4, representing commercial capacity, and divide the result by 2.

"(6) To the current physical capacity, expressed in cars, apply the final percentage arrived at under paragraph 5, and the result will be the current mine rating in equivalent 50-ton cars.

"(7) Mines should be permitted to order cars up to the limit of their physical capacity. The distribution, however, should be made among mines in proportion to their mine rating, as arrived at under paragraph 6, or their order if less than mine rating under paragraph 6. If during any monthly period of distribution any mine or mines shall be unable to load its or their proportion of the available cars, the

Hatfield Removes Chafin's Appendix—by Agreement

Don Chafin, Sheriff of Logan County, West Virginia, had his vermiform appendix cut out by one of the Hatfields March 29. This cutting affray had the Sheriff's approval, however, as he went to hospital at Huntington to have it done by a member of the Hatfield family, Dr. Henry Drury Hatfield, formerly Governor of West Virginia and one of the most skilful surgeons in the state.

Bitter political feuds which have marked the relations of Chafin and Hatfield in the hectic history of Logan County were forgotten, and Dr. Hatfield smiled broadly when he announced the operation was a complete success. The appendix was placed in a bottle of alcohol for preservation.

A radio receiving station has been placed in Sheriff Chafin's room at the hospital.

average shall be distributable among the remaining mines in proportion to their mine rating, or order if less than rating.

"(8) In the absence of special provision the commercial capacity of a mine not in operation during the last period of car surplus would, in terms of percentage be expressed as 0 per cent. Adding this percentage factor to 100 per cent, representing physical capacity, and dividing by 2, would give a resulting percentage factor of 50 to be applied to current physical capacity for determining the mine rating. In other words, the minimum mine rating for any mine would be 50 per cent of the current physical capacity."

No New Cause Found for Castlegate Blast

Exhaustive investigation in the burned-out workings of No. 2 mine of the Utah Fuel Co., at Castlegate, Utah, has failed to reveal any new light on the cause of the explosion of March 8 which killed every man in the mine, according to B. W. Dyer, district engineer for the Bureau of Mines. The attempt of the fireboss to clear out a small quantity of gas in room No. 2 off the sixth left entry is still assigned as the primary cause. The explosion spread from there.

The investigating board was composed of Dan Harrington, supervising engineer of the U. S. Bureau of Mines; Mr. Dyer, Fred K. Gaethke, engineer in charge of mine rescue car No. 9; H. E. Mann, engineer in charge of mine rescue car No. 2; R. M. Magraw, general superintendent of the U. S. Fuel Co.; William Littlejohn, general superintendent of the Utah Fuel Co., and John Crawford, coal mine inspector for the State Industrial Commission.

Findings of the board will be submitted next week to the Industrial Commission and the Bureau of Mines, said Mr. Dyer.

Reach Wage Agreement for Northern West Virginia

An agreement has been reached upon a new contract between the representatives of Northern West Virginia Coal Operators Association and the United Mine Workers. As a result there will be no suspension in the district, wherein almost 28,000 miners are employed.

The conference was held in the Southern Hotel, Baltimore, and the negotiations lasted more than two weeks. It was announced at the close of the conference on Friday, March 28, that all basic day and tonnage rates now in force had been reaffirmed. Certain changes were agreed upon in relation to working conditions, these being for the most part concessions to the miners.

Day wage rates reaffirmed ranged from \$6.74 to \$7.26 a day. Tonnage rates vary from 62.7c. for machine loading to 87.6c. for hand work. The new contract is based upon "the Jacksonville agreement," just ratified in the Central Competitive Field. It is expected that the agreement reached in Baltimore will be indorsed by the operators association and the miners' union.

Barrett Resigns; Trouble Looms in Eastern Canada

Silby Barrett, provisional president of the United Mine Workers for the eastern Canada district, has presented his resignation to William Dalrymple, representative of the International board of the U. M. W. The resignation will be acted on at a meeting of the International board in Indianapolis, to be held in the near future. William Huston has been appointed acting provisional president until the International executive board meets.

The resignation follows the rejection of the agreement negotiated with the operators in eastern Canada. Barrett had advocated the ratification of the agreement. The vote of the miners, however, exhibited a substantial plurality against acceptance. Once more tension is felt in the eastern Canada coal fields, which have been in continuous ferment for the past four years. With the liberation from prison of J. B. McLachlan, deposed secretary-treasurer of the district, the tension is growing. Another strike looms ahead in the mines owned by the British Empire Steel Corporation.

Safety Council and Mining Institute Meetings

The next regular conference of sectional chairmen of the National Safety Council will be held at Cleveland, Ohio, Saturday, May 17, following the last of this season's meetings of the engineering section of the council, May 16.

The Coal Mining Institute of America will hold a meeting in Pittsburgh, Pa., Dec. 3-5, according to an announcement by H. D. Mason, Jr., secretary-treasurer.

Wage Agreement Deferred In Kanawha Field

The conference of union operators and the scale committee of District 17, United Mine Workers, scheduled for Friday, March 28, at Charleston, was postponed owing to the absence of miners' representatives at a meeting with northern West Virginia operators at Baltimore. Much uncertainty prevailed, therefore, as to whether it would be possible for union operators and miners in the Kanawha region to get together before the expiration of the old contract on March 31 in time to avert a strike of union miners in that section of the Kanawha field still in union territory, though it was hoped that some sort of an agreement would be worked out.

Early Conferences Barren

At the first conference held at Cincinnati several weeks ago, which lasted two days, the representatives of the miners demanded acceptance of the Jacksonville agreement. The operators refused. Another conference was held at Washington on March 25 but was of short duration, adjournment being taken until Friday, March 28, at Charleston.

The fact that non-union Kanawha operators are paying much lower wages than fixed in the Jacksonville agreement presents union producers with a difficult problem, as it will be impossible for them to compete with the non-union mines if the 1922-1924 wage scale is paid. Comparatively few union mines in the Kanawha field are working at the present time owing to low prices, poor markets and high wages. Whatever may have been evolved between the time this was written and the time it appears in print, it seemed almost certain that the miners would insist that the union operators of the Kanawha field accept the same terms as agreed upon with northern West Virginia operators.

Cut in West Kentucky Hangs Fire Until April 15

The western Kentucky deadlock between operators demanding a 25-per cent wage reduction and miners demanding a continuance of the 1921 scale for three years appears to be softening. Instead of a strike or lockout April 1, the two parties agreed last Friday at Madisonville, Ky., to extend the existing agreement to April 15 while President John L. Lewis, at International headquarters, tries to determine some way to change the situation. It is prophesied that if he will not agree to an agreement cutting wages 25 per cent for at least one year, no agreement of any kind will be signed. The field would then be largely non-union. This negotiation applies only to that section of western Kentucky centering in Muhlenberg County. The western part of the western Kentucky field is already largely non-union although a union contract with several operators, signed last spring, has another year to run.

Southwest Fields Suspend

CHICAGO, April 1—The entire Southwestern district, comprising Kansas, Oklahoma, Missouri, and Arkansas, shut down April 1 pending the outcome of wage negotiations now going on in Kansas City, Mo. There is no evidence of a break in the deadlock between miners and operators. The operators say they will demand a wage reduction and will submit a revised scale after "more important matters now in subcommittee" are disposed of. It is generally understood that unless the miners grant important changes in working conditions the operators will demand a 40-per cent wage reduction. It is predicted that negotiations will run well into the summer.

Lehigh & Wilkes-Barre Co. Pays 200 per Cent Stock Dividend

Having formally approved the plans of the board of directors to increase the capital stock of the company from \$10,000,000 to \$30,000,000, stockholders of the Lehigh & Wilkes-Barre Coal Co. on March 27 voted themselves a 200 per cent stock dividend, payable 100 per cent in common and 100 per cent in preferred stock. The new stock will be distributed April 1 to stock of record March 26.

C. F. Huber, president of the company, in a letter to stockholders, said that the par value of the stock heretofore has not reflected the actual investment in the business or the amount of the investment of the holders of a large majority of the stock.

"From the organization of the company in 1874 to 1909," he said, "no dividends were paid to the stockholders, the company retaining the entire current earnings in the development and growth of its business. On Dec. 31, 1923, the company's surplus exceeded \$17,000,000, the major portion of which was accumulated prior to March 1, 1913, and is invested permanently in the company's business. To bring the company's capital more in line with such permanent investment the board of directors has declared this dividend."

New York City Departments Seek Coal Bids

Bids will be opened on April 8 by the Department of Purchase of New York City for furnishing and delivering to several of the city departments nearly 450,000 net tons of coal and coke. The tonnages required are as follows: No. 1 buckwheat, 206,730 tons; No. 2 buckwheat, 31,630 tons; No. 3 buckwheat, 47,850 tons; run of mine, 89,815 tons; stove coal, 5,630 tons; chestnut, 120 tons; pea coal, 690 tons; Georges Creek coal, 144 tons; coke, 350 tons, and mixed coal (two-thirds No. 3 buckwheat and one-third run of mine), 55,100 tons.

Leon Besson Is Made Kansas Inspector After Furor

Leon Besson is now state coal mine inspector for Kansas, succeeding James Sherwood. His appointment, effective April 1, has created considerable furor in Kansas politics, and marks a victory of the Alexander Howat rebel faction within the United Mine Workers organization in the Kansas district. Besson's appointment by Governor Jonathan I. Davis was challenged by Judge John H. Crawford, of the Industrial Court of Kansas, who voted against the appointment and favored Ernest Shaw, of Weir, Kan., on the ground that Besson had not passed the state mining board's examination. But Judge Crawford was outvoted by the other two members of the Industrial Court, both recent appointees by Governor Davis.

Besson is a socialist and an avowed Howat man in the struggle Howat is making to get back into the miners' union and to win back control of the Kansas district from the union administration at Indianapolis. His appointment was opposed not only by miners of the administration faction but also by many of Governor Davis' own party. Davis was elected Governor on an anti-Industrial Court platform, and his causing his two appointees on that court to appoint Besson inspector without undergoing an examination and a man whose democracy is seriously questioned promises to be an incident of no small proportions in Kansas state politics.

James Sherwood, who has been inspector for five years, will return to employment with the Associated Companies handling mine liability insurance. A year ago the Associated Companies offered Sherwood a position at a tempting salary, but when Judge Crawford told the concern Sherwood was needed on his official job it consented to wait until he had completed his service to the state.

Spent His Long Life Underground

Ten thousand days in a coal mine is the record claimed by "Uncle Steve" Bone, of West Frankfort, Ill., now 71. He was born in England and started working in the mines with his father at the age of seven years. He has worked for forty-nine years in a mine now owned by the Chicago, Wilmington & Franklin Coal Co. Before labor was organized Bone says the contracts were "iron-clad" and a miner could either sign them or get out. He also worked 15 hours a day in some instances in the early days. During his long service in the mining industry Bone has had many narrow escapes, but was never entombed or seriously injured. It is estimated that he has traveled 1,640 miles up and down in the cages and has loaded 139,977 tons of coal. Bone's sons are miners.

Harry N. Taylor

The former president of the National Coal Association now heads the United States Distributing Corporation, which reports net income of \$592,962 for 1923.

More Coal Lands for Henry Ford?

Henry Ford has closed negotiations with the Davison-Connellsville Coal Co. for the purchase of 3,700 acres of coal land in Fayette County, Pennsylvania, and Monongahela County, West Virginia, according to a report from Uniontown, Pa., March 25. The price will reach \$10,000,000, it is said.

Representatives and engineers of the Ford interests have been on the ground some time inspecting the property and the mines, which are in operation. Mr. Ford, it is said, wanted the lands to provide fuel for his glass and subsidiary companies in the Pittsburgh district.

A SPECIAL DISPATCH TO *Coal Age*, March 17, from Salt Lake City, Utah, covering the recent disaster at Castle-gate, stated that R. M. Magraw was superintendent of the Utah Fuel Co. mine. This was an error. Mr. Magraw is general superintendent with the United States Fuel Co., Salt Lake City.

545,400,000 Tons of Bituminous Coal Produced in United States in 1923

Total output of soft coal in the United States in 1923 was 545,400,000 net tons, according to preliminary estimates by the U. S. Geological Survey.

The estimates by states, like that for the country as a whole, are based on weekly reports of cars loaded by the 137 principal coal-carrying roads, furnished through the courtesy of the American Railway Association. These weekly loadings afford a substantial basis on which to estimate the total output because the carriers reporting load about 85 per cent of all the coal produced. Allowance also is made for mine fuel, coal coked at the mines local sales, shipments by water and over certain small roads not reporting.

Many interesting facts are revealed

by the table, the most striking of which are the sharp increase in the output of West Virginia, which for the first time passed the 100,000,000-ton mark, and the maintenance of production in Kentucky close to the high record established in 1922. Probable factors in the high rate of production in those states were the demand for low-volatile coals as substitutes for anthracite for household purposes, and for high-volatile coals for the coke industry. No new high record was established in Pennsylvania, but the 1923 output—approximately 160,000,000 tons—was 41 per cent higher than in the strike year, 1922; 38 per cent higher than in 1921, and about 10 per cent less than the maximum production of 1918.

Estimated Production of Coal in 1923, by States, Compared with 1920, 1921 and 1922.

	(In Net Tons)			
	1920 ^a	1921	1922 ^a	1923 Estimated
Alabama	16,294,099	12,568,899	18,324,740	18,200,000

Virginia	11,378,606	7,492,378	10,491,174	11,000,000
Washington	3,757,093	2,428,722	2,581,165	2,950,000
West Virginia	89,970,707	72,786,996	80,488,192	100,100,000
Wyoming	9,630,271	7,200,666	5,971,724	8,200,000
Other States (b)	159,054	180,468	253,126	250,000
Total bituminous	568,666,683	415,921,950	422,268,099	545,400,000
Pennsylvania (anthracite)	89,598,249	90,473,451	54,683,022	95,444,000
Grand total	658,264,932	506,395,401	476,951,121	640,844,000

(a) Includes output of "wagon mines," for which data were not available in other years.

(b) Alaska, California, Idaho, Georgia, North Carolina, Oregon and South Dakota.

Practical Pointers For Electrical And Mechanical Men

Old Centrifugal Mine Pump Made Good as New

About three years ago a three-stage centrifugal pump was removed from one of our mines because it would no longer deliver anywhere near its original capacity. The mine water had eaten away some of the inside parts and much water leaked from stage to stage. Consequently, much of the water was merely circulated from one stage to another. Like many other pumps which have given a reasonable amount of service this pump was destined to land in the scrap heap. But before finally discarding it we decided to open it and see just what had happened. We expected at least that we would learn something about its design and possibly might find something which we could pass on to the manufacturers for their information.

Not long ago we found an opportunity to open up this pump to see just what had happened. Upon close inspection we found that the separating rings between the various stages were badly

Fig. 1—Original Joint Between Separator and Casing

The shallow tongue in the joint between the space separator and the casing soon corrodes away and leaves considerable space for the mine water to leak from stage to stage.

eaten away at the line where they are fitted to the outer casing. The leakage through these spaces was not unusually large but was sufficient to prevent the pump from generating full capacity pressure and from delivering as much water as its size would indicate. Fig. 1 shows how the separating rings were fitted to the outer casing. It will be noticed that the tongue at the joint extends but a short distance into the groove in the casing; in fact, the dovetailing at the joints was not more than $\frac{1}{8}$ in. When the water started to corrode the metal at the joint it soon formed an easy passageway from one stage to the other. Just as soon as this condition existed the flow of water through the joint increased rapidly and the corrosive action of the water was quickened. The dirt in the water passing through this joint brightened the surface of the metal and thus the

Fig. 2—How Joint Was Opened by Mine Water

Dirt in the mine water polishes the surface of metal thus increasing the corrosive action of the acid in the water. The leakage from stage to stage soon increases when there is a direct flow of water through the joints.

acid in the mine water had little difficulty in eating it away. Fig. 2 shows how the joints between the separating rings and the casing were worn to a considerable width. Further examination showed us that the rest of the casing and pump parts were not unduly worn.

A new casing for this pump would have cost between \$800 and \$1,000, but before buying it we decided we would try to repair the pump. Accordingly the casing was taken to our shop where it was rebored and fitted with rings designed to fill in the space between the stage separators and the casing. These parts are shown in Fig. 3, and it will be noticed that the tongue and lip at the joints were materially increased. The tongue fitting into the casing was made $\frac{1}{2}$ in. deep. To fit the rings securely in position, they were coated with red lead and boiled in linseed oil.

Our repair of this pump was satisfactory as the pump has now been running for about nine months and is still delivering full capacity at a reasonably high efficiency. Just recently this pump has been permanently located in a place where we were about to install another pump of the same capacity. As a consequence we have

Fig. 3—Filler Rings in Place

These spacing rings were placed in position after the casing had been rebored. The deep tongue in the groove makes it much harder for the mine water to circulate in the joints. The saving resulting from this repair was from \$800 to \$1,000.

saved over \$2,000 by this little repair job. Another pump of this same type is now being repaired, and we feel sure we have found a means to materially increase the life of a pump of this type.

J. F. MACWILLIAMS.

Making Power-Line Work Easy and Safe

Linemen are more frequently injured while working at the ground level than they are while working in the air. The injuries may be received in many ways, but most commonly they are due to slipping, tripping, falling, handling tools, or being struck by flying or falling objects.

A few years ago, practically all pole and post holes were dug by hand, and the poles were raised and placed in position with pike poles. With many companies, hole-digging machines have replaced the digging bar and shovel, and pole-erecting derricks have superseded the pike pole and "deadman." Power winches, chain hoists, and auto trucks are now much used in place of the old strong-arm methods which formerly resulted in so many strained backs and blistered hands; but with the introduction of these powerful devices more responsibility fell upon the shoulders of the foreman. Cables and ropes, blocks and slings all had to be strengthened.

The evolution of the auto truck as a vehicle for transporting men, material and supplies has been a revelation. Not many years back, the "heavy gang's wagon" looked like a homeward-bound junk man after a big day's business. The bottom of the truck was filled with a pile of ropes, blocks, hand lines, coils of guy wire and messenger cable and a tangle of miscellaneous wire, both new and recovered.

On top of this would be piled a collection of digging tools and hand tools of all kinds, a dozen or more pike poles of odd lengths, and a couple of cant-hooks. Above this conglomeration would be piled several partly filled wire reels, and above all, half a dozen or more linemen, hanging on by their eyebrows, trying to keep the load under them, while the horses drawing the wagon were traveling in high to reach the plant before quitting time.

Out of this mess came the highly perfected and systematized "traveling stockroom" of today "with a place for everything and everything in its place." Naturally, with system came increased safety. A well stocked first-aid kit is now always at hand, and the cuts, scratches, and sliver punctures, which formerly were responsible for many

cases of infection, are now treated on the job, and the probability of infection is greatly reduced.

With the introduction of labor-saving devices for line work and construction, there has been a consequent reduction in the number of men employed on any particular job. The reduction in the number of men has usually resulted in a "survival of the fittest," and to say that some men are less fitted for line work than others is stating it mildly. Instead it should be said that some men employed as linemen are a positive hazard, not only to themselves, but unfortunately to their fellow workers also.

There are, possibly many times in the course of a day's work when one lineman is compelled to trust his life to another, and often it is necessary that he place this trust in a wholly irresponsible and careless co-worker. While "juggling hot stuff" 30 or 40 ft. above ground, in the vicinity of other live wires or grounded cables, a lineman should not be compelled to work on the same pole with a man who has had a couple of wild nights and feels either like "telling the world" about it or going to sleep on the job.

CARELESSNESS CAUSES MOST GRIEF

The class of men who are attracted by this adventurous life cannot be expected to be recruited from the ribbon counters in department stores, but there are some engaged in the work who might more properly be employed as stunt flyers at an aviation field, or animal trainers with a circus. Carelessness, inexperience, and thoughtlessness cause more grief for the lineman than all of the other possible causes combined. Take the following cases and see in how many you can blame the accident to one or more of these three factors:

A lineman on a pole with a hand ax, placed it on a crossarm while he was changing his position. The hand ax was jarred off and in falling struck a groundman on the shoulder, sending him to the hospital for several weeks. Hand axes should never be taken up a pole.

Another lineman, reaching out from the pole to catch an insulator tossed up from the ground, lost his balance, came into contact with a live wire, fell to the ground, and was badly injured. Tossing up material or tools is against the rules of most companies. The handline is much more reliable, if not quite as speedy.

Here are two cases where a handline caused trouble, but in neither case should the handline be blamed. In the first, a lineman climbed a pole to do some work on a transformer. Instead of taking the end of a handline with him, he called down to the groundman to throw it up. He stood up on the cover of a transformer with his back to the pole in a favorable position to receive the line, but in attempting to catch it, he straightened up and brought his head into contact with a high potential line. Falling to the ground he was killed.

The other accident in which a handline figured was caused by a thrown line becoming tangled in a high potential circuit. In attempting to shake

the line loose, a short circuit burned off one of the line wires. The falling wire struck a lineman working on the pole. He received a shock which caused him to fall, breaking both arms. Neither of these accidents would have happened if the handline had been carried up the pole.

Rubber gloves are usually provided by the company, systematically tested and kept in good repair. Linemen frequently have to be coaxed or threatened by the foreman before they will put them on, and then sometimes they will take them off and tuck them under their belts, just when they need them most. To use rubber gloves as a measure of precaution in the event that the circuit on which they are working accidentally comes into contact with a high potential line, apparently seems to some of them like displaying a weakness, and they would rather take a chance with a high voltage than to run a chance of being "kidded" by the other boys in the gang.

RUBBER GLOVES BETTER THAN HARP

The lads who are poking fun would make one believe that gloves should be worn with a swagger stick and monocle, but there are different kinds of gloves and different kinds of jobs. Rubber gloves are unwieldy and not exactly pleasant to wear, but at the worst they are much better than a wooden overcoat.

Take this case: After making the claim that he could "eat 220-volt stuff," a lineman climbed up on a steel frame building to cut down a 220-volt service. Standing on the grounded steel work, and without gloves, he cut the line. The moment the jaws of his pliers touched the copper, his grip froze to the handles and he was killed before he could be freed.

There is another reported case where a lineman was badly shocked as he cut into a 110-volt wire while he was standing on a lawn that was wet from sprinkling. In another quite recent fatality, a lineman was killed by 110 volts. He was connecting a three-wire 110/220-volt service on the pole and had the middle or neutral wire under his left arm close up to the shoulder. While tapping the service to the line, he received a 110-volt shock through his pliers, right hand, right arm, and chest, which killed him before he could be released.

PULLING DEAD LINES EVEN DANGEROUS

Many serious accidents have been reported where men were pulling wires or cables while standing on the ground and the lines came into accidental contact with high potential circuits. This class of accidents has become so frequent and serious with certain companies, that they are contemplating requiring groundmen to use rubber gloves while handling wire or cables which are in any way exposed to accidental contact with live circuits at any voltage.

Once in a great while safety belts break and linemen fall, but more frequently they fall because they are not using the belt. The safety belt is frequently changed from one location to another as a man changes his position on the pole, and here lies the greatest danger. In passing the strap around the pole or over an arm there is often

greater liability to come into contact with high potential circuits, and "looking ahead" in this case is important.

I would offer this advice to linemen: Do not do your work automatically or subconsciously. Think as you go and "think safety." This may be illustrated by a story of two men working on an 11 kw. line, painting the cross arms yellow. One was splashing along with his mind miles away, when he unconsciously reached up and hung his paint pail on the 11,000. His partner called his attention to what he had done. He looked at it for a moment and then said: "Well, if I hung it there I guess I can't take it off," and he did.

Do not forget, if you are a lineman, you are a member of a team, just as much as though you were a ball player—with this difference: If you make an error you may not be able to play again tomorrow. In no game is team work required more than in the game of "juggling juice." There is an old saying: "Linemen never grow old," I would qualify that by saying: "Careless linemen never grow old," so "keep your eye on the ball" and don't get too close to the plate.—G. E. Kimball in *Safety News*.

Rules Being Established for Radio Antennas

In the past few years much has been said and written on the subject of the hazards of antennas used in radiophone receiving installations. Many people have sought to convey to the minds of the untechnical the idea that radiophone antennas are invariably a menace, arguing that every wire elevated or suspended in space and connected at one end to the earth is likely sooner or later to be struck by lightning.

To counteract this impression, the radio selling organizations supported a campaign the aim of which was to present to prospective purchasers statistics that would prove the risk to be negligible. Representatives of some of these organizations felt that insurance companies, underwriters committees and inspection bureaus were overestimating the hazard in the interest of bureaucracy and against the interest of the radio equipment companies.

The situation now is clearing as the public learns that the National Electric Code, recognized by fire-insurance companies, specifies methods of wiring, including lightning protection, which should be followed if damage to life and property is to be reduced to a minimum.

Care in Handling Copper

Copper cannot be given the same rough treatment that iron, steel or brass will stand; it requires some important precautions in its handling and application. It fails quickly under localized stresses. Sharp bends, rough or nicked edges in copper straps or wires, limited movement to take care of expansion and contraction, are all points especially to be guarded against. This is particularly true when the copper is subject to quick, sharp blows or vibration, such as are common with locomotive motors.

Problems In Underground Management

Water Cartridge May End Powder Risk And Bring Down Coal in Lumps

Will Not Cause Dust or Gas Explosions, Shatter Roof or Coal Ribs, nor
Develop Poisonous Gases—Small Cartridge Only
Two Inches in Diameter

MORE than one effort has been made to introduce the hydraulic cartridge into the coal mines, and correspondence recently received shows that it still has many advocates who are anxious to get in touch with the concerns which are making it. The cartridge must stand up, of course, under the severe conditions it has to confront.

It is not easy to shatter coal, rock or concrete and do it by main force without the advantage of impact and have the equipment remain uninjured and ready for continuous work. That B. C. Beachamp, of the Demolition and Construction Co., 72-74 Victoria St., London, S. W.-1, the owner of the Tonge hydraulic mining cartridge says his device will do. Its ability to crack concrete as shown in the illustrations seems to satisfy that point, at least in a degree.

The other difficulty is in the making of the hole for the cartridge. Powder and dynamite go into small holes. The hydraulic cartridges have needed more room. One, at least has required or preferred a slotted hole. This device needs a hole 2 in. or 4 in. in diameter depending on the size of the cartridge. This size is by no means insuperable, the smaller hole being quite of usual dimensions.

The hydraulic mining cartridge consists of a strong steel cylinder or cartridge-shaped body containing a number of small hydraulic rams or presses which work at right angles to the axis of the body. These rams were formerly of duplex or telescopic form, thereby having a longer travel. For practical work the solid ram has proved adequate to all requirements, being also somewhat simpler. The cartridge is used in conjunction with a pneumatic, steam, or electric drill.

A hole of a suitable diameter, slightly larger than that of the particular size of cartridge being used, is drilled to the required depth in the material being broken. The cartridge is inserted in position, and liners, or packing pieces of flat iron bar about $\frac{3}{8}$ in. thick, are placed between the heads of the rams and the concrete circumference of the hole. All is then ready for "firing."

A charge of about a quart of water is required. The tank containing this is

connected by a rubber tube to the suction side of the cartridge pump. This pump has two handles, the smaller of which is attached to the pump piston. Operation of this handle in and out alternately draws in water from the suction side and forces it into the cartridge head. An air exhaust valve is left open until the cartridge head, tubing, and pump are full; it is then closed.

With the apparatus full of water it is now impossible to operate the small handle direct, and the second, and larger one, is brought into use. It consists of a screw device, which as it is tightened up forces water into the cartridge head past a non-return valve. As the operator continues to work the pump, therefore, the pressure behind the rams in the cartridge head gradually "builds up," until finally the material to be broken cracks and then gives way.

The hydraulic pressures usually employed in working the tool are from three to five tons per square inch, although much higher pressure could be used if required. However, as the

collective area of the rams multiplied by the hydraulic pressure per square inch indicates a total bursting pressure of from 60 to 240 tons, depending on the size of the machine used, it is clear that no higher operating pressures are needed for all practical purposes. One of the early applications of the machine was the lifting of 200-ton masses of concrete to permit of a chain being passed below them for removal.

The cylindrical head of the cartridge is made of various diameters and lengths, and is provided with five, six, or eight press rams, according to the size of the tool, the larger sizes having the smaller number of rams. For concrete work the 4-in. diameter cartridge has proved most useful. Recently, to meet the requirements of lighter work, a baby cartridge of slightly over 2 in. diameter has been developed.

It is interesting to note that the cartridge was used in raising the two British warships that were sunk during the war in the Zeebrugge Canal to blockade it. By means of the cartridge the concrete with which these ships were filled was easily removed and the hulls were floated.

The hydraulic cartridge was invented by a mining man, Mr. Tonge, for use in the coal mines. Its use for demolishing concrete and rock is a new development, but shows the power with which it can be made to operate. It has the advantage that where it is used explo-

Water Power Applied to the Breaking of Concrete

Hydraulic mining cartridge breaking 50 tons of concrete with a single "shot" at Lots Road Power Station in London, England. The pump by which this was effected is seen near the under side of the arch.

Sketch Showing Construction of Hydraulic Mining Cartridge

A, ram; B, retaining plate; C, passage; D, connection pipe; E, piston; F, piston rod; G, supplementary hollow rod. The small handle is used to fill the pump with water by the usual method of reciprocation. When the cartridge is filled—it only needs a quart of water—the screw pump is used to provide the final compression thus causing the plungers to move out with almost irresistible force. Note the small water reservoir with its rubber pipe. This latter, of course, never receives any pressure, except that of the reservoir.

sives are not needed. This is a distinct gain as it removes the dangerous powder magazine, which has already claimed many lives. It also saves the danger and expense of the powder trip and all the dangers connected with the handling of powder, fuse and detonators at the mine face.

It, further, is safe in a gaseous place. Even permissible explosives are not safe in gas if an overcharge is fired. The possibility of powder being dropped or discharged unburned into the coal is avoided as well as all the dangers of deteriorated explosives. A long train of accidents is thus avoided.

Where the hydraulic cartridge is used

no coal-dust explosion can be charged to the breaking of the coal and the quantity of fine dust formed will be decreased, however that is a minor matter as undercutting makes plenty of dust. The coal is not shattered, nor are the adjacent ribs of the roof, making the roadways more permanent and safe and reducing the need for timber. Neither poisonous gases nor smoke are formed. Where ventilation is defective deaths from the first have occurred and the health of the miner has often been affected adversely. The smoke of explosives is particularly undesirable especially during working hours. With the hydraulic cartridge "shooting" can be done at any hour without fear of

accident, delay or discomfort. The "shot" is made in about five minutes, and as will be seen the equipment is light. No tests of this cartridge have been made in America but it is being extensively tried we understand in the mines of Great Britain, and it is being used quite generally, we are told, in the urban demolition and construction work in that country. Care, of course, would have to be taken to arrange the cartridge so that it would break the coal down in sufficiently small pieces that the miner would not have to reduce the coal to small sizes in order to load it into the car. Only experience will determine the true value of the water cartridge.

Chunk of Waste Stops an Inaccessible Leak

By E. S. WADE

Superintendent, Beech Bottom Mine Power, W. Va.

In the Beech Bottom mine of the Windsor Power House Coal Co., near Power, W. Va., an extensive sump a short distance from the main headings was drained by a plunger pump. A 3-in. discharge line led from the pump through an airway to a borehole 175 ft. away, which carried the water against a head of 65 ft. to the surface.

The roof in this mine is "rotten," and consequently comes down in large falls, unless it is timbered, properly. The airway mentioned, unfortunately, was not so timbered, with the result that many falls occurred in it. One of these broke the discharge line of the pump. An attempt to locate the break would have been both difficult and dangerous.

What was to be done? Water in the basin rose rapidly and the discharge borehole was no longer available. The shortest distance from the pump to the surface by way of the entries is about 1,200 ft. and at least three days would be required after the pipe was obtained and brought into the mine to lay such a line. I was at a loss to know what to do and asked a representative of a pump manufacturer for his advice.

He suggested that the discharge end of the pump be opened and a piece of waste, the size of one's fist, be placed in the line. His theory was that the waste would follow the path of least resistance. Consequently when it reached a break in the pipe, it would rush into the opening, where it would

serve as a plug, held in place by the pressure of the water inside the pipe, which naturally would be many times greater than the atmospheric pressure on the outside.

He was right. I tried his scheme and it worked perfectly. This emergency repair afforded me an opportunity to lay a new permanent discharge line.

Does Oxidation of Pyrite or Of Coal Cause Mine Fires?

Pyrite, says J. Ivon Graham, in a paper read before the South Staffordshire and Warwickshire Institute of Mining Engineers, has been credited for the past three centuries with causing the spontaneous combustion of coal. It is now clear from recent researches that in some cases the oxidation of coal is the cause of spontaneous combustion and that in others the oxidation of pyrite is to be credited as being the cause.

Winmill, says Mr. Graham, has indicated that the pyrite of North Staffordshire which oxidizes rapidly is found in a finely divided state and that the lump pyrite in the Barnsley bed that remains untarnished for years, when crushed to a fine powder oxidizes rapidly at (86 deg. F.), in fact as rapidly as the North Staffordshire material, whereas particles that will be retained on a 30-mesh screen and pass through a 10-mesh show only a slight absorption of oxygen.

Winmill has shown that twice as much heat is evolved in the oxidation of pyrite as is generated in the oxidation of coal when an equal quantity of oxygen is absorbed. Further Win-

mill's tests show that the rate of oxidation of pyrite is doubled for a rise of 10 deg. C. or 18 deg. F., an acceleration in the rate of heating of pyrite in excess of that resulting with the oxidation of coal.

Some pyrite from the Ballachulish state quarries which showed no evidence of tarnishing rapidly oxidized when broken up into small sizes. Massive pyrite from Cornwall and radiated pyrite (marcasite) from the chalk at Folkstone showed a similar action. Hence it seems obvious that pyrite when broken fine is readily susceptible to oxidation.

Reducing Resistance of Air To Cage Movement

General recognition has been given to the fact that the movement of

cages interferes with the passage of air in the shaft. It also adds to the work of the hoist. Recently experiments have been made showing that mine cages when traveling at the maximum speed increase the static strain on the rope 8 to 21 per cent. This lowers the actual margin of safety from 10 to 7 and a writer in *Braunkohle* advises that air resistance be reduced as shown in the illustration especially for deep shafts and high hoisting speeds.

Production And the Market

Unrelieved Dullness Pervades Coal Markets; Contracting Lags; Lake Opening Lacks Promise

The coal consumer's little game of "wait and see" is being carried to such lengths that stagnation prevails in the coal markets of the country. Everyone continues to hold back to see what will happen, but nothing happens. Even the closing of contracts which ought to be in evidence at this time is conspicuously backward, and that despite the low levels that prices have reached. Running time at commercial mines has dropped to three days a week or less in most fields, southern Ohio working at less than 20 per cent of capacity. In the Standard field and in eastern Kentucky many mines have closed down, and many others are soon to follow suit, as a strike is expected in the latter field April 1. An indefinite suspension is looked for also in the Southwest pending the negotiation of a wage agreement. Central Pennsylvania and northern West Virginia have ironed out their differences, the existing agreement having been reaffirmed in each case, with minor modifications. An open-shop pact has been signed for four years between the union and the Kentucky-Tennessee operators' association.

Preparations for the opening of the navigation season on the Lakes lack the usual hopeful anticipation. With about 3,500,000 tons of coal on the docks at the Head-of-the-Lakes March 15, compared with 900,000 tons at that time a year ago, there is likely to be an oversupply when navigation opens. As a consequence a considerable falling off in early lake traffic as compared with last year is more than probable.

Midwest Markets Stagnant

Coal Age Index declined 3 points to 173, as of March 31, the corresponding average price being \$2.09. This compares with \$2.13 on March 24.

A slight firming up of steam coals is the only feature that has tended to relieve, in a measure, the deadly

dullness that has settled over Midwestern markets. Though a number of screening contracts expired April 1, very little contracting is going on, consumers still having supplies sufficient to last several weeks longer. Running time at commercial mines averages about 2½ days a week.

Kentucky markets have developed further weakness, due to mild weather and lack of orders from retailers, and more wage cutting is reported in the non-union districts of eastern Kentucky. Eight thousand idle empty coal cars on sidings in the Cincinnati district bear eloquent testimony to the dullness of the market thereabouts. There was a spurt of activity in the Southwestern district, featured by heavy buying on the part of railroads and industries, due to the expected shutdown during the wage parley. The Colorado market was reasonably active, thanks to some cold weather, but the reverse is true of Utah, where the mines are working less than two days a week on an average.

Sluggishness All Too Evident

Sluggishness characterizes the trade in Ohio, and there is no evidence of preparations for rush of early cargoes up the lakes such as was the case last year, when the docks were cleaned up. Pittsburgh is finding it difficult to meet competition from some of the West Virginia and Kentucky fields, which are able to quote lower prices due to wage cuts. Trade in New England and on the Atlantic seaboard remains dormant.

Production of bituminous coal during the week ended March 22 amounted to 9,309,000 tons, according to the report of the Geological Survey, which was 318,000 tons less than was produced during the previous week. Output of anthracite totaled 1,804,000 tons, a decline of 137,000 tons compared with the preceding week, when 1,941,000 tons was mined.

Estimates of Production

(Net Tons)

BITUMINOUS

Week ended	1922-1923	1923-1924
March 8	10,628,000	9,617,000
March 15 (a)	10,428,000	9,627,000
March 22 (b)	10,424,000	9,309,000
Daily average	1,737,000	1,552,000
Coal year to date	417,168,000	532,016,000
Daily average to date	1,389,000	1,780,000

ANTHRACITE

March 8	2,049,000	1,882,000
March 15	2,057,000	1,941,000
March 22	2,126,000	1,804,000
Coal year to date	54,478,000	91,118,000

COKE

March 15 (a)	410,000	308,000
March 22 (b)	384,000	316,000
Calendar year to date	4,270,000	3,367,000

(a) Revised from last report. (b) Subject to revision.

Midwest Dullness Continues

There was little to relieve the chronic dullness in Midwestern markets during the past week even though steam coals firmed up a trifle. An effort to force screenings business was made by jacking the price of southern Illinois 1½-in. stuff to \$2, and 2-in. coal to \$2.15, but even this did not drive much business into the open. A good many screenings contracts ran to April 1 and the holders of some of these agreements have more fine coal on the ground, which evidently is going to carry them several weeks further. By May 1 a real stiffening of fine-coal prices is expected.

The prospective shutdown in the Southwestern region beginning April 1 last week was looked upon by Illinois producers as a source of some business in Missouri, Kansas and Nebraska. This argument was worked to the full on steam purchasers, who insist upon making no contracts now but who say they will be ready to do so in a month or six weeks. Very little contracting is now going on.

Domestic business is slow indeed throughout the Midwest region. Fag-end business is all there is at retail yards, especially after a period of fine balmy weather opened during the latter part of last week. Many mines closed

down in southern Illinois, as well as in the rest of Illinois and Indiana on April 1. Running time at the average commercial mine has not exceeded 2½ days a week.

Mines in the Mt. Olive district are carrying a large number of "no bills" in prepared sizes, which is the result of a small demand for domestic tonnage by reason of the prevailing mild weather. Two and one-half inch and 3-in. lump is being quoted in the St. Louis market at \$3 per ton mine, while prices in the surrounding territory outside of East St. Louis and St. Louis switching districts are 25c. per ton lower, or \$2.75 per ton. Domestic egg and domestic nut are difficult to move at any price.

In the Standard field the only size finding a ready market is screenings, which are quoted at \$1.10@1.30. A number of mines already have suspended operations and others are contemplating doing so on April 1. Those in operation are fortunate in getting two days per week working time.

St. Louis Trade Is Duller

Mild weather has caused a decline in retail interests, resulting in a decidedly inactive market. Dealers are reducing their stocks to a minimum, anticipating lower prices April 1. The country demand is largely for cheaper grade

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	March 31	March 24	March 17	April 2
Index	173	176	179	252
Weighted average price.....	\$2.09	\$2.13	\$2.16	\$3.07

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

coals, but only a small tonnage is moving, the country dealer taking the same view as the city dealer. There is some interest being taken in anthracite, but orders are withheld awaiting the new circular.

Kentucky Market Soft

Milder weather and lack of retailer orders has further weakened the Kentucky coal market, until \$2.75 is the top price quoted on the best spot coal in the state, while there has been some distress stuff selling at ridiculously low prices. Eastern Kentucky mines in the non-union districts are reported to have done some more wage cutting, which is causing much dissatisfaction among miners, but it is a case of lower production cost or close down.

Revised prices of eastern Kentucky coal show block at \$2.50@\$2.75; lump, \$2.25@\$2.50; egg or nut, \$1.75@\$2; mine run, \$1.25@\$1.75; and screenings, 75c.@\$1.15, while western Kentucky is asking \$2.75 for 6-in. block; \$2.40@\$2.50 for egg or lump; \$1.75@\$2.15 for nut; \$1.40@\$1.85 for mine run, and 90c.@\$1.25 for screenings.

Western Kentucky has no business to speak of and many mines are closing, even though a strike was expected in most of the field April 1. Operators report that a good many mines are down and that others are working a day to a day and a half a week, the few that are working two days being considered as "sitting pretty."

Northwest Trade Is Dead

Dock conditions at the Head-of-the-Lakes are bad. Stocks on docks March 15 are placed at 3,500,000 tons, of which approximately 1,500,000 is free coal. Very little has gone

out in the past six weeks, and at present it looks as if there would be an oversupply when navigation opens. This time last year the docks held only about 900,000 tons. The railroads are taking what coal they can. The docks would be working only two or three days a week if it were not for them.

Prices of bituminous are the same as last week, although the market is weaker and reductions are likely. Dock companies at Duluth have word not to cut, as any one of a dozen possibilities might help the market.

A cut of \$1 in anthracite pea coal has been announced. The remainder of the anthracite market is firm. This cut is because of oversupply and makes the dock price \$10. Little anthracite is in demand. Nut is cleaned up, but a small amount of stove seems to bob up every now and then. Buckwheat and Pocahontas are both at a standstill. Anthracite substitutes are dead. Briquets can be had at \$10, and coke at \$9.50 to \$10.50, depending on size.

The coal market is in a state of stagnation at Milwaukee also. Little or nothing is doing. Demand is only for fuel for immediate use. The weather continues mild. Representatives of dock companies are in the East consulting the powers that be as to future supplies and also as to the extent of the spring cut in prices, which is expected to be promulgated about the beginning of April.

Southwest Shutdown Coming

The last week of March was an active one through the Southwestern district. The prospect of Kansas, Oklahoma, Missouri and Arkansas mines being closed indefinitely pending a wage agreement by the operators' and miners' scale committees, which opened a joint meeting in Kansas City March 28, brought heavy buying by railroads and larger industries of industrial sizes. The slight surplus of lump and nut accumulated as a result of the increased demand for screenings is causing little worry. It is expected to be cleaned up before long. Mines have been working full time. Kansas prices are unchanged.

The market in Colorado continued reasonably active last week, due to the cold weather. Dealers are fairly well loaded up with small orders on the cheaper grades. Higher grades and anthracite are not popular and a number of unbilled loads of all kinds are reported at the mines. Colorado mines worked an average of twenty-four hours last week. There has been no change in prices since March 1.

The market in Utah continues sluggish in spite of a short cold snap which moved a little retail coal. Mines are working less than two days a week on an average. The demand, such as it is, is for slack, which is hard to get on account of the short working time. No bill cars are on the tracks and operators are doing their best to keep the mines open.

Cincinnati Market Panicky

April 1 prices perhaps are the most interesting of the year's quotations in Cincinnati, as they throw a light for several months to come. During the past week the Louisville & Nashville contracts were let, and those of the Big Four, Norfolk & Western and Chesapeake & Ohio are being parceled out, indications showing that as the really large tonnage is concerned a \$2 basis, or close to it tells the tale. Smokeless circular prices name \$3.50 for lump and egg, \$2.50 for nut, \$2.25 for mine run and \$2 for screenings. Unlike other seasons this represents the figures of the producers. Off grades are being sold below the market, however, and some mine run is being sold with a guarantee that it will contain 50 per cent of the lump and egg. The state of trade is panicky and inclined to be twisted this way or that with the slightest influence. Forty per cent of the mines in Hazard, Harlan, Elkhorn, Big Sandy and in some of the C. & O. fields are down. Still the production, according to interchange figures, continues on the high ratio marked up in the past few weeks. Specialized coals are quoted as follows: Lump, \$3@\$3.50; egg, \$2@\$2.75.

All branches of the Columbus coal trade continue to be quiet, producers as well as jobbers playing a waiting game. Large consumers apparently are waiting until railroad fuel contracts are awarded before coming in, as the prices quoted in the railroad contracts probably will control in commercial business. Quite a few roads have asked for bids and something in that line may be expected

soon. Domestic trade is extremely quiet and retailers are buying only an occasional car to piece through. Slack is weak, owing to the falling off in demand from public utilities. Many Ohio mines are being closed down and output is at a very low point.

As the coal year nears its close, the market situation at Cleveland seems to grow correspondingly worse. Operators and jobbers say that inquiries continue noticeably absent and the market exceedingly dull. It is said that the railroads throughout this section have on hand at least 100 days' storage, and consequently some contracts will not be renewed coincident with their expiration March 31. No contracting of any magnitude is taking place, and it will be an open market proposition pretty generally for a time. The eastern Ohio field as a whole is working less than 50 per cent of full time, and is showing a decline each week. A large number of cargoes are afloat at the lower Lake docks ready to go forward at the opening of navigation.

Production in the Pittsburgh district has been dropping rapidly, chiefly on account of the disappearance of domestic coal. Spot market prices are unchanged except for further declines in slack. It looks as if little contracting will be done, except in special grades of gas coal, consumers preferring to buy from month to month.

Sunny weather at Buffalo has prevented any spurt in the coal trade. As the season is now far advanced the possibility of a weather market seems to be past.

New England Markets Pessimistic

In New England the steam coal market has suffered further reverses. Not only is there an absence of any but scattering spot purchases but prices have declined in pronounced fashion on certain of the high grades. This is the case to a limited extent with quality coals from central Pennsylvania, but most notable are the successive slumps in the figures quoted on Pocahontas and New River both f.o.b. vessel at Hampton Roads and at this end on the dock for inland delivery. Through the trade there is a note of pessimism, and buyers can hardly be relied upon to show much interest in futures under the heavy conditions that now prevail.

For some reason a large share of the smokeless output a fortnight ago was pointed to tidewater, due doubtless to slackening conditions in the West, and large accumulations have been the result. A week ago it was stated that nearly 400,000 tons of Navy Standard coal was either at or en route to the piers, and prices have softened correspondingly. Coal that ten days ago was being held at \$4.50@ \$4.65 has sold down to \$4.25, and in a few instances there have been distress lots disposed of at levels materially lower.

In sympathy with market conditions at Hampton Roads, there has been a similar scaling down of quotations on cars Boston. A few leading factors have run spot coal down to \$5.50 per gross ton, or within easy range of the lowest level last season. Somewhat earlier there were competitive bids from \$6.10 to \$6.30 for Pool 1 grades for delivery through a 12-month period, but already these figures are being discounted and further depression in values can only be conjectured.

All-rail and via the Philadelphia and New York piers there is very little steam coal being dumped, output from central Pennsylvania being hopelessly outclassed by Hampton Roads coals on the current price basis, except within restricted areas.

Seaboard Consumers Out of Market

Buying of soft coal at New York is practically at a standstill. Reserves are such that consumers are not purchasing and there are many mines which it is believed, will be closed soon after the beginning of the new coal year. Contract making is slow and many consumers have not renewed their old contracts nor made new agreements for the coming twelve months. As a rule renewals have been on a lower basis and with the Jacksonville agreement ratified by the miners it is expected that consumers who have no contracts will continue to buy in the open market. Further weakening of the market is indicated in the purchase last week by the U. S. Shipping Board of 1,500 gross tons of soft coal equal to either Pool 71 or Pool 9 at \$4.48 alongside vessel, New York, as compared with \$4.84 for the last previous purchase. This is on a basis of about \$1.80 net ton f.o.b. mine.

The wage scale conference of central Pennsylvania operators and miners has had no effect on the market at Philadelphia, as it was known that the non-union production is more than enough to take care of all current needs. In addition stockpiles are so large that the market would not miss the union tonnage for a long while to come. Producers are after contract tonnage, offering attractive figures on contracts to run from one to three years. Inquiries have dropped to almost nothing.

There is not much of encouragement in the soft-coal trade at Baltimore at present except an increasing export movement. Industrials are buying in small quantities only for the major part, and the usual flood of contract inquiries at this time of the year is largely lacking. Prices remain low.

Anthracite Business Flat

Reductions of 50c. per ton on the various sizes of hard coal with the exception of broken and barley were announced by two of the large producing companies on March 29, making the prices of these companies for egg, stove and chestnut sizes \$8.25, for pea coal \$5.75, and for No. 1 buckwheat and rice \$3 and \$2 respectively. It was expected that the other companies would announce their schedules for April 1 early this week, and that similar reductions would be made. Buying at New York was practically at a standstill except as to current needs. Coal moved so slowly from the terminals that some of the companies loaded boats to await orders for delivery after April 1, while some retailers, anticipating lower prices, had already advertised a cut in their delivery costs. Independent operators are for the most part quoting company circular or lower in order to move their prepared coals, with the average sales being made at below company prices. Pea coal moves slowly, but the steam coals are in fair shape, with barley leading in demand. Philadelphia reports trade as quiet, if not flat. The consumer is waiting for lower prices and is buying very lightly on that account. Retail yards are well filled, with probably more of pea than anything else. It now looks as if the April price for family coal will be \$14.75 for the large sizes and \$11 or \$10.50 for pea.

Foreign Market And Export News

Wage Negotiations Upset British Market; Output Continues to Gain

Business and prices in the Welsh coal market are inclined to be erratic on account of the unsettled labor position and the scarcity of tonnage. The south Wales situation is very strong and the majority of the collieries declare that they cannot accept further orders for delivery before Easter.

European business shows no indication of improving at the present and it is reported that much business is being lost to Germany. The violent fluctuations of the franc are further complicating deals between French buyers and British sellers. The entire field is disturbed by the negotiations proceeding between the unions and the operators.

Much the same conditions prevail in the Newcastle market, where tonnage is exceedingly short and many collieries are forced to make concessions to effect immediate clearances. The European business has fallen off considerably. The Swedish State Rys. are in the market for 70,000 tons best steams for April-June shipment, and one of the French railways is asking for 20,000 tons of coking coals for April-June shipment.

Production by the British collieries for the week ended March 15, a cable dispatch to *Coal Age* states, was 5,778,000 tons, according to the official reports. This compares with 5,742,000 in the week ended March 8.

Industrial and Household Coals Active in French Markets

French collieries are booked beyond capacity for industrial fuels and the demand for house coal continues active. A shortage of trucks has impeded coal traffic lately, this being due partly to the intensive use of trucks in the Sarre and Ruhr mines for conveying coal toward the inland area districts.

Imports of British coal have been rather small of late, prices remaining

firm at the shipping docks. With the pound at 115, selling prices are unusually high.

Importers and briquet makers situated along the coast have asked the government for equal treatment in the matter of reparation and Sarre coals in order to make up for the absence of British coals, on which prices are prohibitive. The government having given instructions that Ruhr coal be transported by sea and that Sarre coal be conveyed through France, importers and briquet makers of the littoral want a hand in selling reparation coal rather than leave it to Strassburg merchants, for instance.

In Belgium, the price for Ruhr metallurgical coke has just been fixed at 170 francs per ton (raised by 5 francs) dating March 1 (or about 149 francs in French currency).

Hampton Roads Market Dull and Weak; Outlook Bright

Business is dull on the spot at Hampton Roads, with many old orders being filled and old contracts being worked out in advance of the new contract

period, April 1. The price of coal is weak, and little new buying is reported.

Coastwise and overseas movement, which had been hampered by storms that held up shipping, is again gaining ground. South America has been getting a number of substantial shipments, but mostly on old contracts.

The tone of the market is weak, but the outlook for better business is still bright, shippers expecting little activity in the spot market until after April 1.

Three Roads Balk at Conditions For Clinchfield Lease

The Carolina, Clinchfield & Ohio Ry. has added its protest to those of the Atlantic Coast Line and the Louisville & Nashville against the conditions raised by Commerce Commissioner Hall as a basis for the lease of the Clinchfield by these two lines. Attorneys for the three roads assert that if these conditions are enforced the consummation of the lease will be impossible.

"The case," says the brief filed by the Clinchfield, "is distinctly different from the case of the Central-Southern Pacific, from which these proposed conditions have been copied. . . . In the Clinchfield case the resulting investment and market value for the Clinchfield stock is one of the vital considerations involved in the making of the proposed lease. The stockholders of the Clinchfield have held their investment for many years with practically no returns and consequently, have had little, if any, available market for the same. The making of the lease will result in an assured dividend on the stock, with the usual effect upon the investment value of and market for the same."

Approves Lehigh Valley Control of D. S. & S.

The Lehigh Valley R.R. has been granted permission by the Interstate Commerce Commission to acquire control by lease and stock ownership of the Delaware, Susquehanna & Schuylkill R.R. The decision was of significance only in that it marked the carrying out of one of the provisions of the segregation decree. The Lehigh already owns the stock of the D. S. & S., a ten-mile line in the coal region of Pennsylvania penetrated by the parent road.

C. & O. to Build 3,000 Cars

Construction of 3,000 hopper cars in its own shops, it is reported, is being considered by the Chesapeake & Ohio R.R., and the company is said to be in the market for 30,000 tons of steel to be used in the work.

Railroads Order More Cars

Railroads of the United States on March 1 had 45,074 freight cars on order, of which 15,632 were coal cars, according to report by the Car Service Division of the American Railway Association. This was an increase of 19,684 cars compared with the number on order on Feb. 1. During February, 11,537 freight cars were placed in service, making a total of 27,729 installed during the first two months this year. Of the cars installed during February 4,841 were coal cars. The railroads also had on order on March 1 457 loco-

motives compared with 439 on Feb. 1. Locomotives installed in service during February totaled 214, making a total of 485 installed during January and February.

Virginia Ry. Income Climbs

Net income of the Virginian Ry. for 1923 was \$3,671,444, as compared with \$3,408,032 in 1922, according to a preliminary report made public yesterday. Operating revenues were \$20,328,347, compared with \$19,009,443 in the previous year. Expenses increased from \$12,439,391 in 1922 to \$13,611,420 in the year just closed. The total assets of the company are listed as \$134,672,098, in comparison with \$122,235,544 last year.

Association Activities

Coal producers in the Broad Top District have formed the **Broad Top Coal Operators' Association**, the main purpose of which is to conserve coal properties by approved methods of production and distribution. H. H. Lineaweaver, of the Economy Domestic Coal Co., of Philadelphia, and Schipper Brothers' Coal Mining Co., Six Mile Run, was elected president; W. W. E. Shannon, of the Shannon Co., Dudley, vice-president, and W. L. Scott, of J. M. McIntyre & Co., Six Mile Run, secretary-treasurer. The organization, which is composed of a score of the largest operators in the region, plans to co-operate and coordinate its efforts with those of other trade associations, and with governmental agencies in the furtherance of all projects affecting the industry. The formation of the body is looked upon as an effort to increase the domestic use of Broad Top

The annual election of officers of the **Indiana Bituminous Coal Operators' Association** of Indiana was held in the offices of the Terre Haute Chamber of Commerce recently. All officers who have served for the past year were re-elected, as were the members of the executive board as follows: President, E. D. Logsdon, of the Knox Consolidated Coal Co., Indianapolis; Vice-President, W. P. Zimmerman, of the Zimmerman Coal Co., Terre Haute; Secretary-Treasurer, P. H. Penna, Terre Haute. Members of the executive board are as follows: Hugh Shirkie, Shirkie Coal Co., Terre Haute; M. L. Gould, Linton Coal Co., Indianapolis; George H. Richards, Lower Vein Coal Co., Terre Haute; Homer D. Talley, Fort Harrison Mining Co., Terre Haute; Mr. Logsdon; Mr. Zimmerman; David Ingle, Ayrshire Coal Co., Evansville; A. M. Ogle, Vandalia Coal Co., Terre Haute; W. J. Freeman, Green Valley Coal Co., Terre Haute; Simon Zellers, Knox Consolidated Coal Co., Indianapolis; John A. Templeton, Templeton Coal Co., Terre Haute; J. C. Kolsen, Jackson Hill Coal Co., Terre Haute; James Moore, Crescent Coal Co., Evansville; H. M. Ferguson, Ferguson Coal Co., Clinton; John T. Connerly, Miami Coal Co., Chicago, and James B. Pauley, J. K. Deering Coal Co., Chicago.

At the annual meeting of the **Norfolk Retail Coal Dealers' Association**, March 18, Oscar B. Perebee, vice-president and treasurer of the Nottingham & Wren Co., was elected president of the association to succeed W. L. Petty, president of George W. Taylor & Co. Other officers of the association are: B. T. Griffin, of Griffin Brothers, vice-president; G. C. White, of C. B. White & Brother, secretary and treasurer. Walter D. Rodgers, executive secretary of the National Retail Coal Merchants' Association, was the principal guest at the meeting. Arrangements were made for a large delegation of Norfolk coal men to attend the annual meeting of the National Coal Association at Bluefield, W. Va., June 4, 5 and 6.

Industrial Notes

The **Rome Wire Co.**, which purchased all of the capital stock of the Atlantic Insulated Wire & Cable Co. in 1922 and which has since operated the plant, is to transfer the machinery of the plant from Stamford, Conn., to Rome, N. Y. Additions will be made to the plant at Rome and the entire business will be managed from that city.

Gellatly & Co., Oliver Building, Pittsburgh, Pa., have been appointed distributors for Post-Glover products, which include Homanite steel resistance grids and W. & W. starters, for the middle and western Pennsylvania districts. **Coffin & Smith**, Board of Trade Building, Scranton, have been appointed Post-Glover representatives in the anthracite district.

George E. Evans, one of the directors of the **Joy Machine Co.**, manufacturers of the Joy coal-loading machine, has announced the purchase by his company of the plant of the Colburn Machine Tool Co., at Franklin, Pa., for the purpose of manufacturing the Joy coal loader. The price paid for the Colburn plant was \$300,000. The monthly output from the plant is expected to be 25 loaders per month. The Joy company has already taken possession of the plant, which had been idle for several years, and expect to begin production this month.

Brady-Warner Coal Corporation is equipping its Abrams Creek Mine at Oakmont, W. Va., with a rotary dump and rope and button retarding conveyor furnished by the Fairmont Mining Machinery Co., Fairmont, W. Va.

Coming Meetings

Canadian Retail Coal Association. Annual meeting, April 3 and 4, King Edward Hotel, Toronto, Ont., Can. Secretary, B. A. Caspell, Brantford, Can.

American Institute of Electrical Engineers. Spring convention, April 7-10, Birmingham, Ala. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

American Welding Society. Annual meeting, April 22-24, Engineering Societies Building, 33 West 39th St., New York City. Secretary, W. M. Kelly, 33 West 39th St., New York City.

National Exposition of Coal Mining Equipment and Machinery of the American Mining Congress. May 12-17, Cincinnati, in conjunction with the annual meeting of the National Coal Association.

National Coal Association. Annual meeting, May 14-16, Cincinnati, Ohio. Executive Secretary, H. L. Gandy, Southern Building, Washington, D. C.

Pennsylvania Retail Coal Merchants Association. Twentieth annual meeting and exposition, Commercial Museum, 34th and Spruce Sts., Philadelphia, Pa., May 22-23. Secretary, W. M. Bertolet, Reading, Pa.

International Railway Fuel Association. Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

The American Society of Mechanical Engineers. Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

American Wholesale Coal Association. Annual convention, White Sulphur Springs, W. Va., June 3-4. Secretary, G. H. Merryweather, Chicago Temple Bldg., Chicago, Ill.

The National Foreign Trade Convention. June 4-6, Boston, Mass. Secretary, O. K. Davis, 1 Hanover Square, New York City.

National Retail Coal Merchants' Association. Annual meeting, Hotel Virginian, Bluefield, W. Va., June 4-6. Secretary, Walter D. Rogers, Transportation Building, Washington, D. C.

Illinois & Wisconsin Retail Coal Dealers Association. Annual meeting, June 10-12, Delavan, Wis. Secretary, I. L. Runyan, Great Northern Bldg., Chicago, Ill.

American Society for Testing Materials. Annual meeting, Chalfonte Hotel, Atlantic City, N. J., June 23-27. Secretary, Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

News Items From Field and Trade

ALABAMA

The Black Creek Coal & Coke Co., recently organized, has begun development on its 7,000 acres of Black Creek coal, the new mining camp being known as Thermal, located on the Louisville & Nashville R.R. in the northern end of Jefferson County. A slope already has been sunk for several hundred feet and work is progressing on a tippie and washery capable of handling 800 to 1,000 tons daily. Both inside and outside equipment will be of the most modern design, electrically driven. Houses for employees will be erected at once. A spur from the Louisville & Nashville R.R. to the mining site is about completed. It is stated that a byproduct coke plant is to be built later on. All of the officials of the company are experienced mining men, E. M. Tutwiler, Sr., being president; Priestly Toulmin and T. W. Morgan, vice presidents; Priestly Toulmin, Jr., secretary; E. C. Morgan, treasurer and general manager, and Herbert Tutwiler, assistant to the president and sales manager. Head offices are located in Birmingham.

The Alabama Power Co. is adding a third unit of 20,000 kw. to its Gorgas steam plant, which will bring the plant up to 70,000 kw., or 95,000 hp. Hundreds of mining operations and industries in this district obtain power from the Alabama Power Co. and this standby steam plant affords uninterrupted service during low water periods.

The Blount County Mining Co. has been incorporated at Oneonta by J. G. Rowell and E. H. Rowell with a paid-in capital of \$10,000 to engage in the coal-mining business.

COLORADO

During the month of February Colorado mines produced 884,881 tons of coal, this being a decrease of 31,121 tons as compared with the production for the same month last year. The total number of men employed in and about the mines for the month was 13,338.

ILLINOIS

The Consolidated Coal Co., of St. Louis will likely shut down Mine No. 9 at Murphysboro in the near future according to reports although there is a considerable tonnage of good coal still unmined. Driving of entries has been stopped. Water from the Big Muddy River broke into this mine two years ago, costing the company a considerable sum of money. The company has land yet unworked near Murphysboro and will probably sink a new mine north or east of the town in the future.

George F. Getz, president of the Globe Coal Co., Chicago, announces the election of C. R. Campbell as vice-president of the company, in charge of the bituminous coal department, effective, April 1, 1924. Mr. Campbell was with the John A. Logan Coal Co. and formerly was vice-president of the Consumers company.

The Prosperity Coal Co., 343 S. Dearborn St., Chicago, has been incorporated with a capital stock of \$20,000, to produce coal and other minerals. Incorporators are J. W. McElvain, J. I. McTaggart and T. H. McElvain.

The Crerar-Clinch Coal Co., of Chicago, has closed the Dale mine at Herrin. The same company operates mines at Johnston City and Du Quoin and is opening a new strip mine which may become one of the largest in the Du Quoin field.

The mine at Valley View owned and operated by Sackville & Wynn has been closed, probably until next fall. The mine is the largest near that place.

INDIANA

The Hickory Grove strip miners, of Terre Haute, who have been on strike since Jan. 2, recently returned to work, the officials of the mining company having signed the Terre Haute agreement with the officials of the United Mine Workers. The Hickory Grove mine employs about 45 miners and has a capacity of about 250 tons per day. The mine is located about one and one-half miles east of Riley. Following the

attempt of the miners to organize the company continued to operate with other men until about three weeks ago, when the mine was closed down.

M. S. Weills, N. G. Wallace and Joseph Mullikin have bought at receiver's sale the property and assets of the Sugar Valley Coal Co., of Terre Haute, for \$98,801.22. The buyers filed with the receiver, Clem J. Richards, a written request that the property be conveyed to the Macksville Coal Co. The sale was made subject to liens on the coal company's property and assets, which, with receiver's compensation and expenses, total the purchase price.

The Comet Coal Co., Evansville, capitalized at \$50,000, has filed articles of incorporation with the Secretary of State. The company will develop and mine coal and other minerals. The directors of the company are Fred J. Stock, Boonville, and Charles W. and Frederick B. Cook, both of Evansville.

KENTUCKY

Late reports on the actions of the adjourned Kentucky Legislature indicate that with the exception of passage of the bill making script transferable and negotiable at face value, and certain slight changes in the Workmen's Compensation law, there wasn't much legislation that will have any effect on the coal trade.

The Kentucky Utilities Co., of Louisville, one of the Insull interests, which is supplying most of the mine power in both the eastern and western Kentucky coal fields, is planning a new hydro-electric operation on the Cumberland River, near Burnside. The same interests are putting in a mammoth hydro development on the Dix River, in central Kentucky, which will supplement the present power facilities, and another large steam plant at Pineville.

The Chickasaw Coal Co., of Madisonville, capital \$25,000, has been chartered by James D. Overall, Blayne C. Mitchell and J. Basil Ramsey. Overall is an experienced large operator.

The Pond Creek Pocahontas Coal Co. for 1923 reports net profits of \$19,353, or 15c. a share on the capital stock. The company's net current assets are \$909,953 and net current liabilities of \$280,123, leaving working capital of \$629,830.

MARYLAND

The new \$200,000 plant of the Anthracite Fuel Corporation, at Fait Avenue and Eight Street, Highlandtown, is about completed. The plant, the first unit of which will consist of four buildings, will be used for the manufacture of coal briquets and will be the only establishment of its kind in Maryland. The completed structures consist of manufacturing, administration and storage buildings and a power house.

MASSACHUSETTS

The Island Creek Coal Co. reports net profits of \$2,722,545 for 1923 after all charges, taxes and preferred dividends, equal to \$20.39 a share earned on the common stock outstanding. In 1922 net profits were \$3,440,350, equal to \$26.44 a share on the common stock. The general balance sheet showed net current assets of \$6,013,271 against net current liabilities of \$1,528,687, leaving the company working capital of \$4,484,584.

MINNESOTA

The Duluth, Missabe & Northern Ry. will add another coal-handling bridge to its Duluth dock, making four in all. The new bridge will serve as an auxiliary for one which is called upon for almost continuous service now. It will serve the west side of the dock. The bridge and equipment will be installed by the Mead-Morrison Co., Chicago, and the electrical equipment by the General Electric Co., of Schenectady. It will cost about \$200,000. The dock has a storage capacity of 650,000 tons and the bridge will increase the handling capacity 25 per cent.

Charles Beuglet, Duluth sales manager for the Northwestern Fuel Co., has undergone an operation at Rochester, Minn.

MISSOURI

Harry Scullin, president of the Scullin Steel Co., St. Louis, Mo., and associates are reported to have an option on 41,000 acres of land in the Raccoon mountains, containing approximately 20,000 tons of iron ore and 9,000 tons of metallurgical coal to the acre. Plans include building barges and tow boats to handle the raw material.

Roy Williams, of New Orleans, has succeeded John McDermott as manager at the Clay Coal & Mining Co.'s mine on the Williams farm, east of Excelsior Springs. Mr. McDermott's interests in the mine were bought one year ago by the other stockholders, but he remained with the company March 1, 1924.

NEW YORK

F. G. Wilcox was appointed president and general manager of the Price-Pancoast Coal Co., the Melville Coal Co. and the West End Coal Co., at a meeting of the boards of directors of those companies, March 24, at their offices, 17 Battery Place, New York City. Mr. Wilcox succeeds William L. Allen, who died recently.

The Elk Horn Coal Corporation for the year ended Dec. 31, 1923, reports net profits of \$168,301 after taxes, depreciation, depletion and interest, equivalent to \$1.27 a share earned on \$6,600,000 preferred stock, par 50. This compared with a net loss in 1922 of \$99,906. Directors decided that earnings do not warrant a dividend at this time.

Twining Tousley, formerly associated with Marshall Field, Glore, Ward & Co., has accepted a position with the Coal and Iron National Bank in its new business department. Mr. Tousley has had considerable experience along financial lines, having spent most of his business life in the employ of financial institutions.

Announcement is made that the last of the ten coal- and grain-carrying steamships building in Europe for the Eastern Steamship Co., a Buffalo syndicate, has just been launched at Birkenhead, England, and will be delivered in April. The vessel has been named the Eugene C. Roberts, after the manager of the coal firm of E. L. Hedstrom. The steamers are of about 3,000 tons capacity, and so are fitted to navigate the Welland Canal and the St. Lawrence River. They ought to effect a resumption of anthracite shipments from Lake Ontario to the upper lakes.

Charles Longenecker, formerly sales engineer with the Bonnot Company at Canton, Ohio, has become associated with the Combustion Engineering Corporation, 43 Broad Street, New York City. He will be identified with the recently created industrial department of the Combustion Engineering Corporation. This Department, in charge of H. D. Savage, will specialize in the application of pulverized fuel to industrial work of all kinds.

OHIO

Signs of the times have rarely been more acutely shown than in the past week, when several offices and branch offices bowed to the general condition of affairs in Cincinnati. The International Fuel & Iron Co., which for the past three years maintained an office in the Union Trust Building, announced that it would be closed, and Charles Reese, who has been in charge would be identified with the main office in Pittsburgh. The Kelly's Creek Collieries Co. has closed the office maintained at Cincinnati for over a year and will conduct its Western business from the Charleston office. The Swain Fuel Co. will liquidate. The Western Coal Co. will close within the week. The Co-Operative Fuel Co., a smokeless concern with head offices in Bluefield, W. Va., has closed its offices in the Fourth National Bank Building.

Papers have been filed with the Secretary of State chartering the Branch Creek Coal Co., Cleveland, with an authorized capital of \$50,000 to mine and deal in coal. Incorporators are Frank J. Kelly, E. E. Rodway, Paul F. Colebrook and A. F. Gaughan.

Al Knidler, in charge of sales for the Liggett Brothers Coal Co. for some time, has been appointed Western sales manager for the Three States Coal Co. with headquarters in Cincinnati.

Harry Neilson, who had charge of the Co-Operative Fuel Co.'s office in Cincinnati, is now in charge of the Western sales agency of the Universal Coal Co. in the same city.

N. K. Howard, who was identified with the office of the Old Dominion Coal Co. in the Union Central Building, until it went in the hands of the receiver, is now associated with the Mid West Coal Co.'s Cincinnati office.

M. L. Yuster, head of the Packard Coal Co., of Columbus, who was the individual owner of a small mine near Athens, with 200 acres of coal land, has traded the mine to **D. W. Wallace** for a foundry and machine shop, which has been known as the Athens Foundry & Machine Co. The mine was leased to the New Lexington Coal Co.

OKLAHOMA

The recently formed City Planning Commission of McAlester has set to work on an extensive program of development, which, first of all, contemplates more thorough exploitation and development of the vast coal-mining operations about the city. The coal deposits in Pittsburg County are declared to have a potential wealth of \$30,000,000,000 by engineers who have conducted careful surveys of the extent and depth of the coal veins. The Commission held its first meeting, which took form of a dinner at the Busby Hotel last week, when the commission had as guests ten members of the official party of the Missouri-Kansas-Texas Ry. touring the Katy lines as a public relations committee. The meeting followed an all-day visit of the railway officials to McAlester and the coal fields, during which they held a number of conferences with business interests looking to the creation of more cordial relations between the shippers and the railway company. The railway officials pledged the City Planning Commission every possible assistance in the development of the coal deposits of Pittsburg County. The question of freight rates as they affect the marketing and transportation of coal from this section was gone into thoroughly, and plans for working out more equitable tariff schedules were made. Joint committees from the railway company and the coal-mining interests will frame recommendations for changes in freight rates which will be placed before the Interstate Commerce Commission in an effort to bring about more equitable freight rates for the McAlester district.

The McAlester-Craig Coal Mining Co. has been organized at McAlester, to do a general coal-mining business in development of some leases on coal lands in Pittsburg County. The company is capitalized at \$35,000, and the incorporators are H. C. Clark, L. Clark, and R. B. Cannon, all of McAlester. The company will operate steam shovels and drag lines in surface mining operations.

The Midway Coal Co. of Chelsea, is developing an extensive bed of coal found at shallow depth near Catale, six miles from Chelsea. The company is now operating two large steam shovels in surface mining operations, and is employing more than one hundred men. The steam shovels are running night and day. A prosperous town is being built at Catale, financed largely by the Midway Coal Co. Additional steam shovels are to be put to work at once, it is reported.

The Montezuma Creek Coal Co. has been incorporated in Okmulgee, with a capital stock of \$50,000, by Harlan Read, H. D. Lloyd and others.

PENNSYLVANIA

Employees of the Bethlehem Mines Corporation, a subsidiary of the Bethlehem Steel Corporation, exceeded all expectations in subscribing to the 7 per cent cumulative preferred stock of the parent company, under the savings and partnership plan recently instituted by the Bethlehem Steel Corporation, which includes a bonus to stockholders in continuous service of the company. Out of a total of 6,932 men employed, 5,580 have taken advantage of the opportunity, by subscribing for 11,297 shares. Slickville Mines, under supervision of L. O. Mellinger, led the subscriptions with 98.5 per cent; Johnstown, under a supervision of Frank Horton and Duncan May, came a close second with a percentage of 98.1. Other divisions subscribed as follows: Wehrum, Pa., with 93.5 per cent; Heilwood, Pa., 92.6 per cent; Preston division, W. Va., 86 per cent; Ellsworth, Pa., 64 per cent; and Marion division, W. Va., 44 per cent.

TEXAS

The Marshall plant of the Darco Company, owned by the Atlas Powder Co., of Wilmington, Del., will resume operations at once, it is announced by A. N. Chase, superintendent and J. M. Williams, assistant superintendent and engineer. This is one of the largest plants of its kind in the United States and mines lignite from the extensive deposits owned by the company, the lignite being manufactured into charcoal for the manufacture of powder, and other chemicals taken from the lignite as by-products.

The Sandow Lignite Co., of Rockdale, has begun operating its extensive holdings six miles south of Rockdale. This company formerly was known as the Western Securities Co. and the mine it is now working as the Federal Fuel Co. The new company takes out the lignite by stripping process. One large steam shovel is now at work, removing the earth overlay and it is planned to place one and possibly two additional shovels in the mine at once. The vein of lignite is overlaid by about 30 ft. of earth. Shovels are now operating day and night, and load one carload of lignite on an average of every thirty minutes. A. P. Rudowsky is president of the company and M. R. Reddell is treasurer. John Weed is general superintendent and has charge of all operations at the mine.

UTAH

Castlegate Mine No. 1 of the Utah Fuel Co., which was closed down a few weeks ago and the men transferred to No. 2 mine, where the recent explosion occurred, will be opened right away. Mine No. 2, it is expected, will be in a position to resume operations, if necessary, about the first week in May.

The Blazon Coal Co. is offering \$50,000 worth of common stock. The company is operating property in Wyoming, where it owns 480 acres of leased lands in the Kemmerer district. The company is headed by L. F. Rains, of Salt Lake City, president of the Carbon Fuel Co., and has a capital of \$300,000.

It is expected that a railroad will be built in the near future to the coal beds in Salina Canyon, Sevier County, by either the Union Pacific or the Denver & Rio Grande R.R. The latter company has had concessions for some years, but has failed to act. It is said the Union Pacific is seeking concessions now.

It has finally been decided to conduct a drive for a relief fund for the dependants of the miners who lost their lives in the Castlegate explosion early in March. The drive is approved by the Governor and \$100,000 will be asked.

WEST VIRGINIA

In all there were nine new domestic coal corporations formed in West Virginia during February, with a total capitalization of \$905,000. These companies include the Carver Coal Co., of Charleston, capitalized at \$50,000; Judicial Coal Co., of Clarksburg, capitalized at \$25,000; W. M. Tyree Coal Co. of Huntington, capitalized at \$100,000; Malone Collieries Co., of Grafton, capitalized at \$5,000; Sitnek Coal Mining Co., of Fairmont, capitalized at \$50,000; Trent-Pocahontas Coal Co., of Iaeger, capitalized at \$50,000; Kenova-Lincoln Coal Corporation, capitalized at \$100,000; Sutherland Coal Co., of Morgantown, capitalized at \$50,000, and Howesville Coal Co., of Morgantown, capitalized at \$25,000.

One of the largest deals consummated in some time was that under the terms of which the Wilbur Fuel Co., acquired the plants, properties and assets of the Vulcan Coal Co. and the Eastern Utilities Coal Co., with large holdings in Grant District of Harrison County, for a consideration said to be in the neighborhood of \$1,000,000. The purchase covers 1,198 acres in fee and 368 acres of surface land upon which there is a town of 115 houses. Officers of the newly organized concern are D. J. Carter, of Clarksburg, president; E. J. Lewis, vice-president and treasurer; R. D. Lloyd, general manager; Harry Sheets, secretary. On the board of directors are the above officers and Frank B. Sinclair, of Steubenville, Ohio; H. W. Sheets, R. D. Lloyd, E. J. Lewis, J. M. Carter and D. J. Carter, of Clarksburg.

The Mohawk Coal & Coke Co. has changed the location of its principal office from Welch to Bluefield, and the Tierney Mining Company has changed the location of its principal office from Powhatan to Bluefield.

The Nagolas Coal Co. has been awarded a verdict of \$26,000 in the United States District Court for the southern district of West Virginia in its suit against the Pine Ridge Coal Co., of Detroit, Mich. This suit was the outgrowth of a dispute as to the division of profits arising from business deals in which both companies were interested.

T. J. Collins, chief mine inspector of the Collins interests in southern West Virginia for the last ten years, has severed his connection with them to become identified with the Harman interests in McDowell County as general superintendent of all mines, his appointment having become effective on April 1.

Three tracts of coal land in Ohio and Brooke counties have been conveyed to the Carnegie Coal Co., of Carnegie and Pittsburgh, Pa., by Mr. and Mrs. John A. Bell, of Carnegie, Pa., the consideration involved being approximately \$85,000. A mortgage has been filed by the Carnegie company in favor of the Colonial Trust Co., of Pittsburgh, covering the purchase of the coal tracts and other property of subsidiary companies to the Carnegie Coal Co., showing that \$750,000 has been secured in first mortgage on the properties.

Philip Konrad, of Killarney, has been appointed general superintendent of the mines of the Killarney Smokeless Coal Co., of the Ingram Branch Coal Co. and of the Smith Pocahontas Coal Co. Green H. Nowlan, of Lynchburg, was recently elected president of these companies.

The Simpson Creek Collieries Co., of 1230 Hanna Building, Cleveland, Ohio, of which W. M. Osborne is secretary, has been granted a certificate of authority to transact business in West Virginia.

The Illinois Coal Co. has increased its capital stock from \$300,000 to \$400,000 and the Elm Grove Mining Co. from \$2,400,000 to \$3,000,000.

The name of the Blake-Towson Coal Corporation has been changed to the Blake Coal Co.

CANADA

The Blue Diamond Coal Mines, of Brule, Alta., which are owned jointly by the McIntyre-Porcupine and Timiskaming mining companies, of Northern Ontario, have been closed down owing to lack of orders from the Canadian National Rys. Gordon F. Dickson, the manager, is visiting in the East.

Figures presented to the Canadian House of Commons showed that Canada imported 20,989,953 tons of coal during 1923, of which 20,417,239 came from the United States. Of the latter, 15,511,206 tons was bituminous, 4,905,707 tons anthracite and 2,331 tons lignite. The balance came from Britain with the exception of a few tons from the Philippines and Alaska.

The Consolidated Mining & Smelting Co., the principal user of Crows Nest coke, is said to be making arrangements for the importation of coke from Europe. The company has made arrangements for the shipping of large quantities of concentrate, matte, and base bullion to Europe, and it is said that the boats carrying this material will return laden with coke. The high cost of coke at the Trail smelter has retarded operations for some years, and the company long has considered other sources of supply.

The Princeton Coal & Land Co. has obtained a verdict for a refund of taxation that had been imposed wrongfully during the years 1909 to 1921, inclusive. Though the amount at stake was comparatively small—\$4,102.40—the decision is important in that it is the first case that has been tried under the amendment to the taxation act, which was passed in December, 1922, whereby the Court of Revision may decide upon the petition of any taxpayer who declares himself, by reason of any manifest error in the assessment roll for any preceding year, to have been charged more than 25 per cent over the sum that he ought to have been charged.

Of \$25,000 sent to the mining communities during the recent strike by the administrators of the Charles Garland Fund, (the Harvard Communist who turned his fortune over to the Communists) the bulk was spent in the dissemination of Red propaganda, it is reported. The money was to have been expended in alleviation of suffering and privation among the strikers.

The Ontario Government has instructed counsel to apply to the Dominion Board of Railway Commissioners for an investigation into the whole question of coal rates from Alberta and Nova Scotia, it was announced in the Ontario Legislature.

New Equipment

Electrically Operated Drill And Hammer

A portable tool known as the Syntro electric hammer has been designed to run on 60-cycle current and strike 3,600 blows per minute. It is suitable for drilling through masonry walls, drilling holes for expansion bolts, chipping castings, light riveting and assembly work, chipping and cracking stone, calking pipe, tank plates and so forth. A similar tool designed for 25 cycles which will strike 1,500 blows per minute can be used for heavier riveting. The hammer proper consists of two windings which are energized alternately to impart a reciprocating movement to a movable core or piston, which is the only moving part. In its forward stroke, the piston strikes a tool, which may be a drill, chisel, rivet set or the like. In its backward stroke the piston strikes an elastic bumper in which it stores its kinetic energy until it is moved forward again. The energy stored in the bumper is then returned to the piston on the forward stroke.

To operate the hammer, alternating current is supplied to the two windings to energize them alternately so as to impart a reciprocating movement to the piston, which moves in synchronism with the frequency of the alternating current supplied to the windings. The current alone produces the operating forces to move the piston. No mechanical devices are used.

Electric Hammer Operates on Alternating Current

Wherever electric current is available this little hammer can be used, direct current must be changed to alternating current because the number of blows per minute depends on the frequency. It fills a great need for a hammer where only electric current can be used as a source of power.

The hammer is rugged in construction and aside from an occasional oiling of the piston, needs no attention. The piston is made of special hardened steel and will last indefinitely. A trigger switch on the handle of the hammer starts and stops its operation.

The hammer meets the need of a portable device that can be carried from job to job. It can be connected to any lamp socket and is then ready for work.

The hammer is at present available in three sizes, one weighing 10 lb., another weighing 17 lb., and a third weighing 24 lb. All sizes are available for 110 or 220 volts alternating current of any frequency. The power consumption of the 17-lb. hammer is 300 watts. Two carrying kits are supplied to hold the hammer and a control box, together with a 50-foot extension cord and a complete assortment of drills, chisels and stone points.

High-Pressure Air Blower

The field of usefulness for propeller blowers has been greatly increased by the introduction of the Coppus Vano blower, manufactured by the Coppus Engineering Corp., Worcester, Mass. With the exception of low-duty ventilating fans, propeller blowers have been used almost exclusively for undergrate draft on hand-fired boilers, or with chain-grate and overfeed stokers. The Coppus blower has a screw-blade propeller which delivers the air parallel

to the axis of rotation. With this design the air leaves in the same direction as it enters.

It is claimed that this blower will produce pressures up to 8-in. water gage, and, therefore, can be employed where, until now, only centrifugal blowers could be used.

The efficiency of the blower is about 80 per cent, and the power consumption at constant speed is practically unaffected by variations in the volume of the air delivered or the pressure.

The principal feature of the blower is the stationary guide vane which causes the air current leaving the propeller to be radially subdivided by the individual guide-vane blades and thus be taken up by them without shock. These blades have a curvature increasing in the direction of the rotation of the propeller which concentrates the air current and gives it further acceleration inside of stationary guide vanes so that a

Propeller Blower for Forced Draft and Auxiliary Ventilation

This little blower is specially designed to develop high pressure. It fills a great need for auxiliary mine ventilation and stoker draft systems.

considerable part of the pressure is produced in the latter. Most of the end thrust is thus taken up by the stationary guide-vane casing. The air currents into which the flow of air has been subdivided by the guide-vane casing, leave it slightly rotating and with a motion convergent toward the axis so that the smallest section of the air flow is reached beyond the casing.

This blower finds wide application wherever a blower is desired. For forced-draft installations on automatic stokers, several units can be grouped together discharging into an air duct to the wind box of the different stokers or stoker compartments.

Auxiliary mine ventilation can be easily obtained from the single-unit machine having fan and driver on one shaft. However, to deliver air through long pipe lines, high initial pressure is necessary. As it is impossible in mine practice to keep air ducts tight, especially at the joints, the air lost by leakage, which increases with the high pressure, is often of greater volume than the actual air delivered at the discharge end of the pipe. Under these conditions, several Coppus blowers delivering the same quantity of air at 4-in. pressure may be installed in a series of units set at equal distances along the air duct. The losses through leakage are thus reduced to a fraction of what they would be at higher pressures.

Grounding Clamp for Conduit Systems

A solderless aluminum grounding device has been developed by the Neco Manufacturing Co., South Norwalk, Conn. The device has a projecting clamp to which the ground wire may be fastened. It can be readily threaded to a piece of conduit so as to provide an effective ground connection. The manufacturers are now in position to supply the clamps in sizes ranging from $\frac{1}{2}$ in. to 6 in.

Unit Type Air Heater

A new heater has been placed on the market by the American Blower Company, of Detroit, Mich., for use in ventilation systems. The unit heater has an automobile-type radiator through which the air is circulated by means of a motor-operated fan. This device is especially suitable for ventilating systems of offices or warehouses.

Passing the Buck

EVERY new piece of equipment gives a chance to pass the buck, and many a superintendent is a past master in the art. As a result, many a device is condemned for faults which cannot rightly, but can speciously, be charged to it. If the new method or the new machine is imposed from above or from some other department than that of the production head—mine superintendent or foreman—it is liable to be opposed. Every effort is made to charge it with all the stray costs which that operating head desires to dispose of satisfactorily to himself and his reputation.

Most cunningly does he contrive to pass the blame to this interloping introduction, and only patient watchfulness and discrimination will assure a fair trial to the new system or device. That is why a discussion of this matter *in camera*, in a full meeting of all concerned, is advisable, before, after and during the experiment. The facts openly and exhaustively discussed will bring all the merits and demerits to light, place all the details of the experiment where they can be clearly viewed, and promote friendly effort to get the best out of the opportunity.

As a rule, however, executives hear but one side and pass judgment. Did the mine superintendent propose it, it is a success. Did he oppose it, it is a rank failure and the cause of many ills with which it may have only a remote or perhaps no connection? With men of many varying qualities and backgrounds—administrational, mining, mechanical, electrical—no subject has been settled till the judgment of all has been sedulously sought. We can no more determine the value of a piece of equipment by hearing the opinion of one man than we can comprehend the value of a building by showing alone a plan of one floor, a front, a rear or a side elevation. We need plans and elevations from several points of view. Then we shall know at least something about our building, and not until then.

Coal Dust "As Is"

TESTS of coal dust in experimental mines and galleries seem to be of the substance as it might be rather than as it is. No one has taken, we believe, the floor material as it is and subjected it to tests. They have not taken it in its natural depth and coarseness and tried it out. Perhaps it might give a false feeling of confidence, for at any time a different condition might arise.

It might be ground finer, it might be less damp, it might have the finer material on top, it might have less roof scale in it or it might be rendered more noxious by the presence of less locomotive sand. Of course, it would be difficult to reproduce the exact condition in an experimental mine. The floor dust loaded into cars would not reproduce the various vertical and hori-

zontal zones, the lines where scurrying feet had worn a path of comminuted dust and lines where mules had kicked up enough broken bottom to render the dust relatively innocuous.

Still the mines as they are might be simulated better. Dust from the most unfavorable place and travel zone in the mine might be taken and tested. It would be more suggestive of what might be expected than dust which was ground to such a fine, mealy consistency that nothing like it was ever seen underground. It is like taking FFFF and drawing conclusions as to the F variety of black powder.

Finally we might add: Never overprove anything. People always suspect an overstatement. The skepticism of those who see the velvety dust in the experimental mine is a case in point. They do not recognize it as coal, not their coal at any rate. But if you put the material they have daily trodden carelessly underfoot in a sure-enough mine like that at Bruceton and put a buster shot in the face like some of those they know unconscionable miners are using and get a severe explosion, you put real fear in their hearts. This is the stuff they have handled, these are the conditions they face—and in that homely thought lies conviction.

In this connection it may be said that when members of the South Staffordshire and Warwickshire Institute of Mining Engineers visited the Eskmeals Experimental Station in England and viewed an explosion of coal from the Kilburn seam of the Butterley Colliery, Nottinghamshire; L. Holland and H. H. Ridsdale criticized the experiment saying: "We consider it most important that the experiments should be carried out on actual samples of road-dust, large and small, taken from representative roads in the pits of that area."

Wonder What Farrington Thinks About?

THE famous cartoonist who draws an almost daily series of picture "strips" wondering what the cigar Indian, and the Statue of Liberty, the handsome collar ad man and other such notables think about, ought to turn his attention for a moment to Frank Farrington, president of the Illinois district of the United Mine Workers. What *does* he think about these days, anyway? And why has he postponed his state convention for two months to May 13? Farrington's problems typify those of many union miner leaders of the country.

His puzzles are enough to make any man lie awake nights and think. There he is with 90,000 union miners in a solidly unionized state. Not a pound of coal can be dug except under the union agreement continued for three years. Unless the usual sixty or seventy million tons of it are produced in Illinois each year of the three, a vast deal of suffering must be borne by his miners. Thousands of them must be squeezed

out of the industry by shutdowns that have already closed three quarters of the state, and the rebel element in Illinois, long dangerous to Farrington's regime, will have new and effective ammunition to use against him, especially in the union election next December. Although he does not particularly hanker to remain president of the district, he does not want to be kicked out.

But in spite of this danger in the reduction of Illinois coal, what can he do to prevent it? Illinois must have a market or it can't produce. Kentucky, a competitor on the south, is headed for non-unionism in those portions which are not already beyond union control. If it doesn't go all the way, it will at least make union contracts in the western end of the state that far undercut the wages of Illinois. That means a certain loss of market by Illinois. The Southwest district operators are determined to have a contract that will materially reduce costs and they probably will have their way. That will mean more loss of Illinois business in Kansas, Missouri and Nebraska. The Northwest docks are heavily loaded with cheap coal and are in position to stock up again this summer with more good coal at prices that Illinois cannot meet in Minnesota unless freight rates are altered. All this adds menace to Farrington.

What is the logical thing for him to do? He cannot violate the new three-years contract so far as wages are concerned. Therefore, that method of remedying the Illinois situation is out of the question. But, as everybody knows, there are clauses in the working agreement in Illinois which add materially to the cost of producing coal in that state. He could change some of them, thereby enabling Illinois mines to hold certain escaping markets. Thereby, also, many miners would hold escaping jobs. Are most unemployed Illinois miners convinced yet that such a course is necessary? Perhaps they will be by May 13. Perhaps, also, by that time certain outlying districts such as the Southwest will have signed agreements that will establish a precedent for Illinois. Is this what Farrington is thinking about?

Slow Progress in Standardization

IN COAL mines we have not the compelling force for standardization that the railroads have. Each mine stands by itself. There is no interchange of equipment. The cars at the Katastonka mine do not have to be coupled with those at the Katie No. 5, and the cars on the roads of one operation do not have to run on the other. Nor do the Katastonka cars have to be repaired at the shops of Katie No. 5. Consequently, the local need for standardization is not supplemented with the need for intercompany interchange.

It is interesting to note the conditions that favored the adoption by the railroads of the Master Car Builders' coupler. When they standardized couplers many of the railroads were already faced with the necessity of changing their coupling equipment. When the change was made they could just as well go to the standard as to some other kind of coupling. One kind of change was no more burdensome than another. Some standards were helped by the fact that they related to equipment that most of the cars did not have at all and might not have had today if the laws had not compelled its introduction.

Standardization will profit by constant advocacy because mines have often, when bought, only the meagerest of equipment. They need almost entire renovation, and when that is the case the scrapping of the old equipment is more economical than the supplementing of some of it and the saving of the rest. Many a plant thus renovated maintains a foolish standard when it would do better to adopt one that is more general. It is often an alibi and not a real excuse to say that the reason why the gages are diverse is because old mines were bought and they had a narrow gage when the purchase was made.

In many cases it would have been well to take the whole string of cars to the scrap heap. They were not fit to run. In fact they had to be almost entirely rebuilt any way. The tracks could probably have been widened on the old ties. Perhaps the ties were too rotten or too short for that but if that were the case the track should have been condemned. Most of these old gages have been kept because the subject of scrapping the old equipment was not even considered and no standard had been suggested.

However, there are some cases where an attempt to conform to standard would scarcely pay until there is a revolution in the industry. Such a change is likely to come soon. When coal is brought by scrapers or conveyors to the main roadways and the cars do not have to enter the rooms, they will be made larger and when larger cars are purchased the gage can be made standard. Only the track in the main roadways will have to be changed. Today a revision in track gage would mean relaying all the room tracks. That in some mines would be profitable, for the roads in the rooms where laid by miners are so crooked that the safety and economy in haulage that would result from their relaying would pay for the operation. Still it takes more courage to undertake the work if the change would involve all the present trackage and not solely the tracks in the main roadways.

Then again concentration of workings will reduce trackage considerably and make it less costly to change the gage. Every considerable change in method of operation makes standardization more possible and it certainly would be helped if the manufacturers could offer a lower price wherever certain standards were adopted.

It is paradoxical but true that standardization is promoted by a general break in standards. A new development causes a discarding of much of the old equipment, and the tendency is, or at least should be, to adopt at that time standards which till then were little other than an impossible ideal.

Off the Track

WRECKS were a daily occurrence on the railroads of past years. Now they are relatively unusual, and traffic moves steadily. The railroads certainly have profited by the change. But the mines, they still have wrecks. They wouldn't be the same old mines without them. These derailments don't pay dividends, but you would imagine they did by the way the average manager makes provision for them. Many a mine would be making a profit if it did not have to write off so much for the destroyed equipment, wasted time, accidental injuries and repairs consequent on cars and locomotives leaving the track.

Careful timbering in Beech Bottom Mine, Power, W. Va.

Better Methods and Improved Equipment Increase Production at Beech Bottom Mine

By Locating Power Plant at Mine, Cost of Power Is Greatly Reduced—Means Adopted to Reduce Loss of Coal in Mining and to Save Unnecessary Handling of Slate

BY ALPHONSE F. BROSKY

Assistant Editor, *Coal Age*
Pittsburgh, Pa.

CENTRAL stations for supplying power in the coal regions are now being built exclusively so near coal mines that the freight costs on the coal can be entirely eliminated. The disposition to locate power houses at some point on the railroad more or less remote from the mines is now recognized generally to be uneconomical. It is cheaper to transmit power at usual voltages over a transmission line 200 miles in length than to carry the coal to a central station by railroad an equal distance even though thereby it is possible to generate the power more conveniently to the center of load. The advantage of locating a central station at a coal mine situated somewhere near the center of distribution is even more clearly apparent. A comparatively recent development in the Panhandle region of West Virginia furnishes an excellent illustration of this tendency.

Headpiece portrays timbering at the junction between two roads and shows how the Windsor Power House Coal Co. supports bad roof by 60-lb. rails placed at 4-ft. centers.

On the Ohio River, at Power, W. Va., a village located about ten miles north of Wheeling, the West Penn Power Co. and the American Gas & Electric Co. operate the Windsor power station, which has a capacity of 180,000 kw. The station is located in proximity to the hillside tippie of the Beech Bottom Mine, owned and operated by the Windsor Power House Coal Co., a subsidiary of the companies just mentioned. The situation is clearly illustrated in the panoramic view, Fig. 3.

The operation of this central power station calls for a supply of 70,000 tons of coal per month, or say 850,000 tons a year. The Beech Bottom Mine has been equipped to produce coal from a tract of 10,500 acres at the rate of 1,000,000 tons per year. The mine is operating in the Pittsburgh No. 8 coal seam, which in this region is 4½ ft. thick. After making due allowance for probable loss in mining, it is estimated that this tract provides a reserve of 54,000,000 tons of coal, or more than a half-century's supply of fuel for the plant.

Fig. 1—Method of Working Panels

Two sets of eight rooms *AA* are driven up concurrently. When these sets are driven half way up two sets *BB* and two sets *CC* are started. Thus sets *AA* are finished when sets *BB* and *CC* are at mid distance. The pillars are not drawn. The center of the panel is worked out first, which is advisable, for the coal is hauled to both sets of face entries making it unnecessary to save the center of the panel when sets *AA* are completed.

Owing to bad roof, the mines in this region are small producers as compared with operations in other areas of the Pittsburgh seam. The plan of mining at this plant is to drive up rapidly short wide rooms separated by narrow pillars which are abandoned without any attempt at recovery. The present owners of the Beech Bottom Mine profiting by early experience in the operation of this seam and by the use of more modern equipment have increased greatly the percentage of coal recovered. Even though the pillars are still lost, a big saving is made because the rooms are all completed before a squeeze comes and prevents further mining.

A brief reference to the character of the overburden will serve to explain the peculiar roof conditions encountered in the operation of the mine. In the Pan-

handle region of West Virginia at least and particularly in the Beech Bottom Mine, the coal is overlaid with about 15 ft. of dangerous roof, consisting of a drawslate and laminations of coal and shale with 12 ft. of fireclay having a conchoidal structure. Above this is a great thickness of massive limestone that will not break except over a long span.

Because of this condition operators in the region believed that it was necessary to leave in the mine all room pillars, chain pillars and a large portion of the barrier pillars, for they could not be recovered with safety. Experience has shown that in this section the roof over a 24-ft. room will stay up for about four months when adequately timbered. After that the 15-ft. bed of drawslate, roof coal, shale and fireclay, between the coal and the limestone, weakens and begins to fall.

Any attempt to remove the pillars in the rooms would start a squeeze that would extend over the entire mine, closing the roads and aircourses completely.

When, four years ago, this property was first taken over by its present owners, it was the pronounced intention to equip the mine for putting out the production of from 3,000 to 4,000 tons of coal per day. Old-timers shook their heads knowingly saying, "It can't be done." But they were wrong, as a careful study of the conditions and the adoption of improved methods and equipment have since shown. On Feb. 13, 1924, the output of coal was 3,486 tons, which probably exceeds all records in West Virginia for a single opening on the Pittsburgh No. 8 seam.

At the time the Windsor Power House Coal Co. came

Fig. 3—Panoramic View Showing the Way in Which the Coal Brought Down from the Beech Bottom Mine. A, is the mine tippie; B, mine portal for loaded track; C, mine portal for empty track; D, rock bin; I, traveling crane; J, coal storage yard; K, Ohio River; L, conveyor system.

into possession of the Beech Bottom Mine, the daily tonnage did not exceed 1,000 tons, although the development in the mine was sufficient to have produced a larger output. The new company at once took steps to overcome the obstacles that hindered production. Its officials soon found that, in order to meet the requirements of the power station, the entire mine plant had to be rebuilt, the plan of the mine had to be altered materially, the system of haulage had to be changed and new shop buildings and a modern tippie had to be erected.

In the mine, the plan had been to drive face entries at intervals of 1,400 ft. and butt entries at intervals of 440 ft. On each side of the butt entries, in each of the panels thus formed, thirty-eight rooms were turned and driven 220 ft. long and 24 ft. wide, on 32-ft. centers. It was observed that many of these panels had to be abandoned before all the rooms were driven up and much coal was lost.

The new management decided that there must be shorter and fewer rooms in each panel. The plan adopted was to drive all entries 9 ft. wide. The main entries were to be driven on 40-ft. centers and face and butt entries on 30-ft. centers. The main and face entries were to be driven three or four abreast as conditions might require, the butt headings remaining on the double-entry system.

SPEED UP EXTRACTION TO OUTPACE FALLING ROOF

As shown on the accompanying map (Fig. 1), the face and butt entries were driven at intervals of 1,192 ft. and 350 ft. respectively. This provided for the driving of thirty-two rooms on 32-ft. centers, in each panel, and leaving a barrier pillar $83\frac{1}{2}$ ft. wide to protect each face entry. The rooms were driven 24 ft. wide and 175 ft. long, measuring from the center line of the entry to the center of the panel where they would meet the rooms driven from the adjoining butt entry.

It should be observed, here, that where the room pillars are not to be extracted, there is not the same need of preserving a uniform line across the faces of the rooms. However, as shown on the map (Fig. 1), it is well to work out each panel by driving eight sets of

Fig. 2—Timbering Roof in Beech Bottom Mine

Rooms are driven 24 ft. wide with 8-ft. pillars, the latter not being recovered, because, if the roof is once broken, a widespread squeeze will do immense damage to the mine. The roof directly above the coal is weak; consequently a row of timbers is placed on each side of the track which is laid in the center of the room. The crevicing of the coal is not natural. The coal has been shot and partly loaded out. The shots failed in the middle to bring down the coal but fractured it as shown.

eight rooms each, in both directions, to the right and left of a pair of butt headings. As appears in the first panel at the bottom of the map, the two inner sets of eight rooms each, marked *AA*, are first started. When these have been driven half their distance, the two outer sets marked *BB* are commenced. At the same time, the four inner sets, *CCCC*, driven east and west from the second pair of butt headings are started. By following this system, when the sets *AA* have reached their limit and have been stopped at the center of the panel, the *B* and *C* sets have all been driven half their distance. At that time, the four outer sets *DDDD* are started from the second pair of butts.

It is claimed that this system provides a much desired concentration of the working places along the several butt entries where thirty-two or sixty-four rooms are being driven simultaneously. As indicated on the map, there is no through haulage on the butt entries, the coal from the rooms in each half of a panel being hauled to

Beech Bottom Mine Is Carried to the Power House and How the Rock Is Handled by an Aerial Tram

A, aerial tramway for disposal of rock; *F*, crushers; *G*, power plant; *H*, machine shop and storehouse; *I*, river and rail delivery; *N*, discharge from railroad cars; *M*, delivery from river boats.

the nearest face entry. Though this increases the haul, in some cases, the plan has the advantage that track and wire may be torn up in rooms and on entries as fast as any section is finished.

In the rooms, 20-lb. rails are laid on steel mine ties. The track is carried up the center of each room to facilitate the loading of coal at the face. This is an advantage when the room pillars are not to be drawn. As shown on the map, all room-necks are bottle shaped and only enough coal is left in the entry stumps to hold the room safely open until it is finished.

CARRY LINE OF POSTS EITHER SIDE OF ROOM ROAD

In Fig. 2 is shown a view of the face of a room being driven up. It will be observed that a row of posts lines the track on either side. The posts are set on 4-ft. centers, with an 18-in. cap-piece at the roof. It is common practice also to set a row of posts, on 4-ft. centers, across the face of the room. Though it is safe to set these posts 8 ft. from the face, that distance is often reduced where shortwall cutting machines are used, as this type of coal cutter requires less than 8 ft. of clearance. No room timbers are removed when a room is abandoned.

The roof on butt entries needs but little support, as the roads are driven only 9 ft. wide and are abandoned in less than a year. At some points where the roof may develop weakness, 20- or 40-lb. rails are placed across the entry to give it the needed support. In this manner rails are often used at the junction of two entries and at room-necks to avoid possible trouble from roof falls at such points. In every case, these rails are recovered when the places are abandoned. A rope from the drum of a crab locomotive is first made fast to the rail to be drawn. If necessary, a small stick of dynamite is used to dislodge a supporting timber. The locomotive, which is kept at a distance where it will be out of danger, is then used to pull out the rail.

As shown in the headpiece, it may happen that an exceptionally heavy fall of roof will make it necessary to place much lagging above the supporting rails. Need for

work of this kind has often occurred at entry junctions. In the figure mentioned, the roof fell and 30 mine-car loads had to be removed and the roof above it supported not only by steel but by lagging. To avoid this difficulty, these large open spans must be heavily supported by steel rails. This is but one of many practices adopted to reduce to a minimum the avoidable gobbing of roof material.

Other practices are supporting the necks of breakthroughs and crosscuts by three wooden posts and timbering all airways by setting posts staggered on 8-ft. centers. The extensive use of steel and wood for supporting the roof has greatly reduced the labor expense of clearing up and gobbing roof falls. Today, though the production of this mine is three times what it was four years ago, the expense for deadwork has been greatly decreased and less slate from falls is hauled out of the mine.

PROVIDING FOR GOOD HAULAGE AND VENTILATION

Referring again to the general plan of mining shown in Fig. 2, the practice has been followed of maintaining every third set of face entries for permanent haulage and ventilation. This set is maintained for an indefinite period depending on the life of the territory to be reached. The intermediate face entries are abandoned as the adjacent panels are finished. Likewise, every fifth set of butt entries is kept open sufficiently to facilitate haulage and ventilation as may be required. Though 60-lb. rails are laid on the main entries and 40-lb. rails on all face and butt entries, as previously stated, 20-lb. rails are used for the most part in rooms.

One of the measures taken to produce an output of 3,500 tons of coal per day is the double-tracking of primary haulage entries and of the more important of the secondary haulage roads. This practice includes the main entries and those face entries that are most commonly used. At present, the main entries have a length of $2\frac{1}{2}$ miles, which will be increased to 6 miles at some later time. The double-tracking of these entries now extends a distance of 6,600 ft. To expedite the work of gathering cars, sidetracks are provided on all face entries at the junction of butt entries. The expense of laying and maintaining these numerous sidetracks is

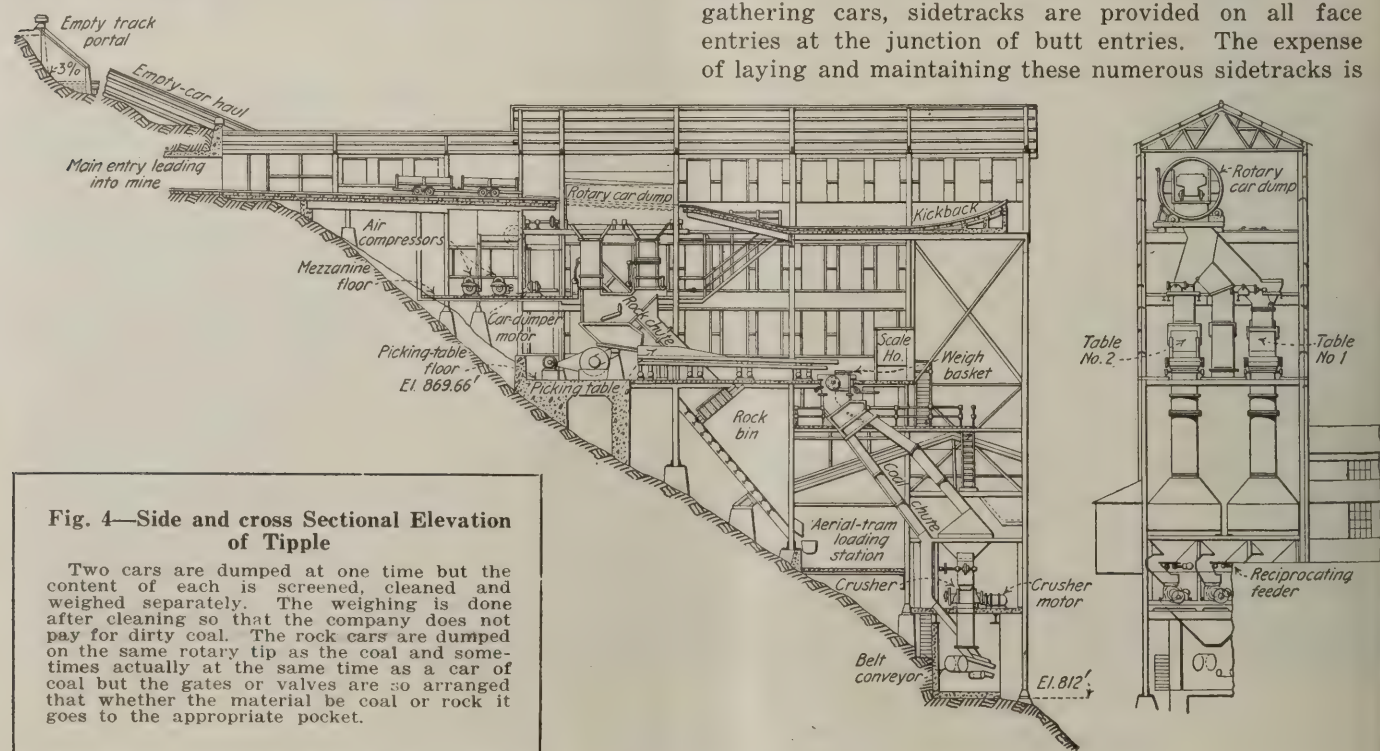

Fig. 4—Side and cross Sectional Elevation of Tipple

Two cars are dumped at one time but the content of each is screened, cleaned and weighed separately. The weighing is done after cleaning so that the company does not pay for dirty coal. The rock cars are dumped on the same rotary tip as the coal and sometimes actually at the same time as a car of coal but the gates or valves are so arranged that whether the material be coal or rock it goes to the appropriate pocket.

Fig. 5—Cars in Revolving Cradle Ready to Dump

The loaded cars come into the dump from what to the observer in this illustration appears as the rear. After dumping they run forward to the kickback and out to the inclined empty-car hoist on the right. The inclined track leading from the rotary dump must impart sufficient momentum to the two cars in tandem to enable them to negotiate the kickback and then clear the shunting switch on their way to one of the two car hauls.

offset by a reduction in the standing time of the gathering locomotives.

On the main haulage roads five 15-ton locomotives are in daily operation. The average one-way haul is 9,250 ft., and each locomotive makes eight round trips between the inby partings and the tippie each day. The estimated capacity of a 15-ton locomotive, running on a practically level track, is forty 2.4-ton cars, making a net load of 96 tons of coal per trip.

Based on an output of 3,500 tons of coal per day, each locomotive would be required to haul $3,500 \div (5 \times 8) = 87\frac{1}{2}$ tons of coal per trip, leaving a good margin for any rock that must be hauled out of the mine. Rated at its full capacity, each locomotive in operation is performing an average of $(96 \times 9,250) \div 5,280 = \text{say } 168$ net ton-miles per hour in the hauling of coal and rock.

Each of the 850 cars with which this mine is equipped

makes an average of two trips a day, between the working face in the mine and the tippie. Estimating the output at 3,500 tons of coal per day and the cars as having a capacity of 2.4 tons, and making two trips a day, or hauling 4.8 tons of coal daily from the face to the tippie, the number of cars required to haul the coal would be $3,500 \div 4.8 = \text{say } 730$ cars, which leaves a fair margin of facilities for the hauling of rock and for bad-order cars lying in the shop undergoing repairs and for others standing in idle places, or otherwise employed in the hauling of timber and track material.

CRAB LOCOMOTIVES USED ON GATHERING HAUL

For gathering haul, sixteen 6-ton and two 5-ton locomotives of the crab or reel type are used. This type of locomotive has been installed, because it is particularly adapted to gathering cars from rooms with the narrow necks that must be adopted at this mine if roof trouble is to be avoided and, again, because it avoids the necessity of a locomotive entering a room where the track is poor and derailment likely.

When a car is derailed by reason of defective track, it can be rerailed with far less difficulty than a locomotive. Each of the eighteen gathering locomotives hauls about 200 tons of coal per day from the working face to the sidetracks where trips are made up to be hauled out of the mine by the larger locomotives operating on the main road.

Mention has already been made of the efforts made to reduce the danger and minimize the expense caused by falls of roof on the roads. During the past year, 7,000 ft. of haulage road have been strengthened by building cribs and supporting the roof with heavy steel rails set in hitches cut in the ribs. Wherever a section of the roof on a main road gives increasing evidence of weakness, these rails are spaced 4 ft. apart.

The importance of this work is reflected largely by the increase during the year of the daily tonnage. In January, 1923, the average daily output was 1,300 tons. This was increased, in January of the present year to

FIG. 6

Shaking Screen Picking Tables

The coal dumped from each mine car passes over one of these two tables, and, in so passing the slack falls through the screen and the dirt is picked out by hand. The clean lump and the slack drop into a two-compartment weigh basket where they are weighed together. The aggregate weight of the two sizes is credited to the miner. Between the picking tables can be seen the chute which conveys the rock from the rotary dump to the rock bin.

Fig. 7—Levers and Valves Controlling Dump

By regulating the valves shown behind the lever control, two mine cars both of coal or one each of rock and coal, are dumped simultaneously and the contents of each kept separate in its passage through the tippel.

2,636 tons daily, or more than 100 per cent. Naturally, there were other factors besides the protection of the roof on the road that contributed to these results, but timbering played an important part.

Of equal importance with the underground improvements that have been described was the construction and equipment of the new tippel building shown in Fig. 4. As appears in this figure, the mine has two openings, one for the loaded cars and another at a somewhat higher elevation for the empties. These are located on a steep hillside several hundred feet above the ground on which the power plant, previously mentioned, is erected. In order to overcome the disadvantage of handling the mine cars in freezing weather, ample storage trackroom, both for the empty and loaded cars was provided under the hill.

CARS ARE DUMPED IN PAIRS BY ELECTRICITY

The loaded cars coming out of the mine are run, in pairs, into an electrically driven two-car rotary dump shown in Fig. 5 which gives a view of a portion of the tippel floor and the arrangement of the tracks leading from the dump to the kickback and returning through the switch to the empty-car hauls. In the background beyond the rotary dump are shown the loaded cars coming from the mine, and on the right is shown the lower portion of the empty-car hauls. Leaving the dump the empty cars run down a short, steep incline to a two-car kickback, returning from which they are shunted to either one of the two empty-car hauls, by which they are taken to a higher elevation so that they will run by gravity into the mine.

The two-car kickback is a feature found at few mines. Its design requires special care to obtain the right vertical curves that will handle two mine cars in tandem and impart to them sufficient momentum to enable both cars to clear the switch leading to the empty-car haul. In order to avoid delay caused by a breakdown of the machinery, this car-haul was installed in duplicate, one unit always being held in reserve to be used in case of accident to the other.

On loaded tracks the inclination of a plane is usually limited to 14 deg., so as to prevent coal from falling off the cars on the incline. This haul, however, was for empty cars only, so it was given an inclination of 23 deg. In consequence it is possible to gain the required elevation in the short distance available between the

switch at the kickback and the head of the graded track leading into the mine.

The tippel is of steel and covered with corrugated iron siding. A novel feature of the two-car rotary dump is the provision made to enable each car when loaded with coal to deliver its load to individual shaker screens and picking tables, each of which has a capacity of 250 tons per hour. By an ingenious arrangement of pockets, chutes and air-control fly gates, a car loaded with rock whether occupying the forward or the rear position on the dump, can be made to empty its load into a 70-ton reinforced concrete hopper, from which the rock is conveyed away by buckets on an aerial tram, as shown in the panorama.

SHAKING SCREENS AND PICKING TABLES

When coal is dumped from the cars, it is carried by chutes to two double-deck shaker screens, which effect the separation of sizes under 1½ in., the larger sizes remaining on the upper deck of the screen, the smaller sizes and slack falling through to the lower deck. From the screen, the lump coal passes onto picking tables where the refuse is picked from the coal and thrown into openings leading to rock chutes on each side of the picking tables.

In Fig. 6, is shown a photographic view of the shaker screens and picking tables with their side pockets, as taken from a point near the scale house. A comparison of this view with the arrangement shown in Fig. 4 will afford a clear understanding of the equipment. Between the two shaking tables appear the rock chutes conveying slate and other refuse to the rock bin below. In the upper right portion of the illustration appears the stairway leading down from the tippel floor. This enables the tippel force to inspect and operate the air-compressor system controlling the wings and gates in the chutes. The head of this stairway is shown on the right of the view of the tippel floor (Fig. 5).

Both the lump coal from the upper deck and the screenings from the lower deck of the shaker screen are conveyed to a double compartment weigh basket, the lump coal having first passed over the picking tables, for the removal of any refuse or rock it may contain. This arrangement is designed to facilitate the weighing at one and the same time of all the coal from individual

Fig. 8—Automatic Recording Scale

Not only is the miner satisfied that the dirt for which he is docked actually was in his coal but he is made certain that the record of weight is correct as vouched for by the recording scale which makes a permanent statement of the weights taken against which can be affixed the numbers on the miners' checks as deposited in the slot provided for that purpose.

mine cars after the refuse has been picked from the lump coal as described.

As will appear from a study of the elevation of the tipple in Fig. 4, a duplicate cycle of operations is provided. The load in each mine car is weighed and dumped before the load of the next car is deposited in the basket for weighing. The two separate sizes are weighed jointly through the agency of automatic recording scales.

AIR CONTROL DUMPS ROCK AND COAL TOGETHER

The dumping of coal and rock at the same time and from the same two-car rotary dump is made possible by a system of control levers and air valves located in an operating room, as shown in Fig. 7. Behind the car-dump levers appear the 3-way air-control valves just below the boards on which are indicated the various directions in which the valves should be turned so as to dump rock and coal from cars Nos. 1 and 2 standing on the rotary dump.

In Fig. 8 is shown a view of the scale house containing the automatic recording device for the weighing of the coal contained in the double compartment weigh basket previously mentioned. After weighing, the coal is dumped from the basket into a bin or hopper from which it is fed by reciprocating feeders to any two of three crushers (see Fig. 4), each having a capacity of

125 tons per hour. Here also, in order to avoid possible delays from breakdowns, a spare crusher unit is provided and held in reserve in case any one of the two crushers may be out of commission.

From the crushers the lump coal is fed to a 30-in. belt conveyor where it is joined with the fine coal and slack which has bypassed the crushers. The entire product is now carried by a series of conveyors that link the tipple with the storage yard at the bottom of the hill and with the power plant adjoining the yard. Provision is also made for delivering coal to the river, if desired, as indicated in the panoramic view previously shown.

A point not to be overlooked in the operation of the mine is the equity afforded all parties by the elimination of tare weight, which has always been the cause of much friction between operators and miners. By screening and picking the coal in mine-car lots before it is weighed, the miner is assured that he will be credited for the exact quantity of clean coal contained in his car. The system offers excellent opportunity for the inspection of the contents of every car of coal coming from the mine. At many operations the inspector has no adequate means of making a satisfactory determination of the quantity of dirty coal in the mine car and this is a cause of a great deal of dissatisfaction.

The Miner's Torch

A Library for Sale

THERE has been much discussion of late in the engineering press and in society proceedings covering the changed status of the engineer in the mining industry. Year by year the mechanical requirements of our mines have increased, and during the last half dozen years this increase has been almost staggering, especially at our coal mines. With the increased use of machinery, mine management and mine planning become more complex and engineering ability becomes more and more a necessity. But it does not follow that because the percentage of engineers at our mining camps is increasing that engineers as a rule are being offered the encouragement that their present importance would seem to justify.

Bearing on the above I want to record an adventure that befel me in a second-hand book store not very long ago.

I had often visited the particular shop and occasionally made purchases, not technical books, however; in fact I had never seen a technical book of any description on any of the shelves or racks. Generally I was drawn to the place when I felt a desire to get away from things technical. On the day in question, as I entered the shop the first thing that attracted my attention was a dozen or so books bound in the sort of bindings that one instinctively associates with books dealing with things technical. My first impulse was to make a hurried exit but this was followed by a desire to find out whether there was a story connected with the offer to sell; why did the man who owned them decide to dispose of them?

You are expecting an engineer's hard luck story just as I did but it is not the kind of a hard luck story that you nor I anticipated. These books were the property of an ex-professor of mining engineering who had given up his profession in disgust and accepted employment as a mechanical engineer with a large manufacturing company; having fully decided that he would never again have any interest in the mining industry, he decided to dispose of his mining library for what it would bring.

I guessed most of the story when I opened the first book and saw his name on the fly leaf, because some three or four years previously I had met the man at a gathering of mining men and he was complaining bitterly at that time about the treatment accorded his graduates by the men who employed them. He intimated then that he felt called upon at times to advise the undergraduates in his department to make a change before it was too late. The owner of the book shop was able to give me the balance of the story, as he had talked to the ex-professor when he came in to dispose of the books.

Many will assume that the professor was not fitted for his task, but I have known several of his students and their estimate of him would not bear out that assumption.

If, in spite of the growing demand for mining engineers, a professor of mining engineering can't conscientiously advise young men to enter the profession, and feels called upon himself to give up teaching, it would seem that a fuller discussion of the subject should be welcomed.

COAL AGE INDEX—A few indexes of *Coal Age* for the last half of 1923 remain. Should you have use for such an index kindly write to *Coal Age* for a copy, which until the present supply is exhausted will be sent free to those desiring it.

Safety Earns Men Four Times As Much as Company

U. S. Coal & Coke Co. Prevents Its Employees from Losing by Accident \$100,000 a Year—Maintains Interest by Bonuses to Bosses

THAT ample room remained at coal mines for improvement in accident prevention was indicated conclusively by Howard N. Eavenson, in an address on "Mine Accident Prevention from the Standpoint of the Mine Operator," before the Mine Safety Conference in Pittsburgh. In reviewing the experiences of the U. S. Coal & Coke Co. in its mines at Gary, W. Va., he stated that during a period of ten years following the adoption in 1909 of the slogan, "Safety the First Consideration," the prevention of accidents saved the company 39 per cent of the compensation it would have had to have paid had the accident rate not been reduced.

Still more striking was the saving to employees during this time, it being equal to the wages earned which otherwise would have been lost had the accident rate existing prior to 1909 been maintained. This saving now amounts to more than \$1,000,000, or an average of slightly over \$100,000 per year. In other words, for every dollar the company saves for itself through accident prevention, it saves \$4.55 for its employees through the elimination of idle periods due to accidents. As time goes on the saving to employees will increase as the number of prevented accidents grows.

These savings were made in a group of eleven mines. They normally produce from 3,000,000 to 5,000,000 tons of coal per year. The roof over one of the beds is a drawslate with many pot holes. Above the other seam, the roof consists of laminated slate and coal.

The first step taken toward the prevention of accidents was the division of each mine into small sections, each of which was placed under the supervision of an assistant mine foreman. The section is of such size

Fig. 1—Training and Education in Accident Prevention

This clearly shows the effect of high labor turnover during the years 1915 and 1916. Its effect is most evident in the minor accidents. It is less pronounced in the serious and fatal mishaps although its influence is visible even there.

CAUSE	INSIDE NO.	OUTSIDE NO.	TOTAL NO.
Defective Machinery Lack of Guards Poor Equipment etc.	□ 4% 8	□ 10% 6	□ 6% 14
Carelessness of injured	61% 113	62% 37	62% 150
Carelessness of others	□ 9% 16	□ 15% 9	□ 10% 25
Violation of Rules by Bosses	□ 8% 15		□ 6% 15
Disobedience of instructions by injured	□ 14% 26	□ 7% 4	□ 12% 30
Disobedience of Company Rules	□ 1% 2	□ 1% 1	□ 1% 3
Unavoidable by injured	□ 3% 5	□ 5% 3	□ 3% 8

Total 245

Fig. 2—Classification of Lost Time Accidents in 1919

Only 3 per cent of total accidents are here classified as unavoidable or pure accidents. Six per cent of the accidents occurring arose from defective machinery. This leaves a total of 91 per cent of accidents caused by carelessness or disobedience of rules or instructions. This represents by far the major field for possible improvement.

that the assistant foreman in charge can visit every working place in it at least once every two hours; no more than 40 men are under his care. He must examine all working places before the men enter them; he does the shooting himself and sees to the safety of his men by prohibiting unsafe practices. He is also instructed to stay on the spot until any dangerous conditions discovered are remedied.

A bonus system based on a sliding scale rewards those assistant foremen who have clean records for specified periods of time. For one month without accident a foreman receives \$5. If he sustains such a record for six or more consecutive months he receives \$15 extra for each month during the period free of accidents. He is given demerits for accidents occurring in his section, but these can be erased from his account, that is, neutralized or counterbalanced by an exceptionally good subsequent record.

This system of intensive supervision has made these mines so safe that the number of fatalities occurring in them is one-fifth the number that occurred prior to 1909. On a tonnage basis, the rate or liability to accident is one-half that for West Virginia as a whole. In Fig. 1 is shown a chart which sets forth the character and extent of accidents from 1909 to 1919.

Labor turnover in these mines is large, and was notably so in 1915 and 1916. This militates against the efforts of the company in the prevention of accidents. Of the miners employed 50 per cent are foreigners, 25 per cent are natives of the region and 25 per cent are native Americans but not of the region.

Lost-time accidents during 1919 are classified in Fig. 2. The purpose of the study which preceded the making of this classification was to ascertain how accidents occurred, particularly as to whether they were due to the carelessness of the men injured or that of others. Fig. 2 shows that unavoidable accidents make up only 3 per cent, and defective machinery is responsible for only 6 per cent of the total number of accidents. The remaining 91 per cent represents a wide margin for possible improvement, all of these being caused by carelessness on the part of either the injured persons or others.

Can Signals Be Transmitted from Mine to Surface And Vice Versa by Ground Conduction System?

Transmitting and Receiving Apparatus Should Be Designed to Resist Adverse Mine Conditions—Importance of Foolproof Equipment—Signals are Most Effectually Transmitted Through Ground That is Neither Dry Nor Too Moist

BY J. J. JAKOSKY*

FOR some time the U. S. Bureau of Mines has been studying underground communication, particularly through rock, ore, and coal, preliminary radio tests being made during the summer of 1922.

The experiments, though they did not indicate any practical method of using wireless waves for underground communications, nevertheless proved clearly that electromagnetic waves may be made to travel through solid strata. The absorption, or loss of intensity with distance, is great for short wave lengths. Long wave lengths are known to suffer less absorption and under certain conditions possibly may be found effective.

The experiments with the geophone were completed two years ago. It is one of the simplest and most portable of signal apparatus. For mine-rescue work, however, it has two major limitations—namely, (1) communication or exchange of information is impossible, except where a predetermined set of signals has been arranged; and (2) extraneous noises such as made by rescue operations, wind, surface, mine vibrations, and such like, limit the use of the apparatus for picking up weak signals. Only a comparatively few prearranged signals may be used for the geophone, because their transmission must necessarily be slow, due to the method by which they are sent, one common method being pounding on the mine walls with heavy rocks or sledges. Variable time lengths such as have proved so effective in telegraphy cannot be used in the transmittal of signals by the geophone.

SIGNAL APPARATUS SET AT STRATEGIC POINTS

The purpose of the work on underground communication is mainly to devise a reliable means of communication for underground use. Should a practical system be devised, it may be advisable as a safety and mine-rescue aid to place such signal apparatus, together with other emergency equipment, at convenient strategic points, such as the faces of entries, on different levels, etc., within the mine where men might be trapped by mine explosions, fires, falls of rock, or other disasters. A study would have to be made of each individual mine, taking into consideration the ventilation, entries and drifts, position of mine, barricading facilities, adjacent workings, present and future mining operations and so forth.

The Bureau of Mines has advocated that refuge chambers be built in the main sections of mines. After an explosion or during a mine fire men might retreat to these chambers and close themselves in until help arrived. Such chambers should be provided with drinking water, canned food and compressed air. In some coal mines in the United States where many explosions

have occurred during shotfiring time small refuge chambers have been provided, and these chambers have saved lives. A practical form of communicating apparatus also placed in the chamber would probably be of great help to rescue parties.

Although somewhat costly in initial installation and maintenance, the present mine telephone is giving satisfaction in most mines. In cases of disaster, such as explosions, fires, falls of rock, flooding, etc., the telephone is often put out of commission or cannot be reached by the underground workers, and that at the time when it is most urgently needed. For this reason the mining industry as a whole is interested in any system of communication—"phone" in preference to code—that can be relied upon in an emergency and many requests have been received to devise such a system.

The solution of the entire mine communication problem is dependent mainly upon the working out of a practical portable mine apparatus of sufficient sensitivity to receive and of an adequate power to transmit over an effective range. It is well known that signals can be transmitted considerable distances through the earth if enough power and a receiving set of sufficient sensitivity be used.

Requirements of mine-rescue radio—The ideal system for mine rescue work and general underground communication would be one where voice transmission and reception is possible. The transmission of code cannot be considered as a general solution to the problem of underground communication. Code however, as regards

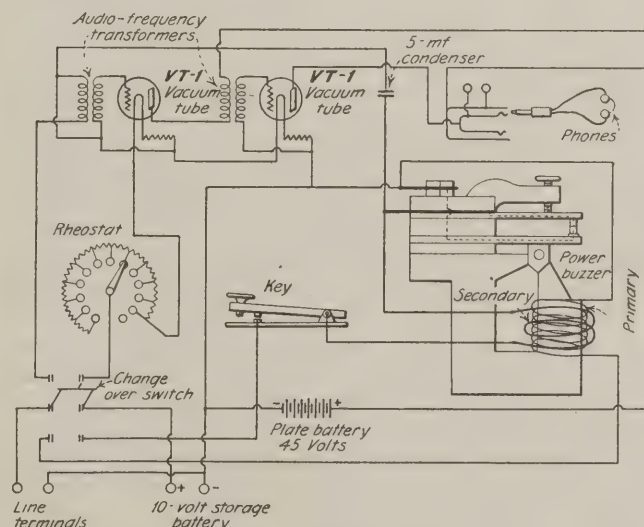

Fig. 1—Transmitting and Receiving Circuits of Tested Signal Outfit

This set consists of the complete equipment necessary for sending or receiving signals. Dots and dashes are propagated through the earth by means of current impulses set up by a power buzzer. Reception is similar to radio detection except that the signals are "picked up" from ground currents set up by the transmitting station.

*Assistant Engineer, Pittsburgh Experiment Station, U. S. Bureau of Mines.

transmission of information, has advantages over the geophone.

To be of practical value any type of apparatus for underground communication must be simple in operation. If high frequencies are employed, requiring tuning to produce resonance, some few fixed frequencies should be used. Two or more different frequencies will allow simultaneous communication by either radio or wired radio during general mining operations. For

Fig. 2—Signals Become More Audible as Distance Between Ground Connections Is Increased

The ground currents set up through the earth spread out in the shape of a sphere when sent from the mine. Hence the greater the distance, within reasonable limits, between the ground connections of either the sending or receiving circuits the louder the signals become.

mine-rescue work during disasters it now seems probable that only one definite frequency should be used.

Vacuum tubes are the only practical method for the successful modulation and transmission of voice signals, but for the transmission of code signals many different instruments can be used.

The apparatus will have to be such as it will be safe to use in an atmosphere containing an explosive mixture of gases. During mine disasters, and especially when barricades are erected, a gas explosion is to be apprehended should unsafe electrical apparatus be used. All mine-signal apparatus should be of an approved and permissible type.

For satisfactory and practicable use in mining and rescue operations, an underground signal apparatus probably would have to be designed to incorporate the following points.

1. The apparatus must be moisture and waterproof, that is, it should be unaffected by dampness and continuous standing in wet mines. Practically none of the radio or high-frequency apparatus being sold today for general amateur and broadcast use would be suitable for such work.

The condensation of moisture on the surface of dielectric and non-waterproofed insulating materials, unprotected windings, condenser end-plates, etc., causes

large current leakages. In numerous tests radio, as well as other high-frequency signal, apparatus left underground 2 to 10 hr. became very inefficient.

2. The apparatus must be durable, rugged, and fool-proof. The entire equipment should be inclosed in a strong case and all delicate apparatus such as vacuum tubes, controller knobs, etc., should be protected.

3. If the mine apparatus is to be of practical use it must be easy to maintain in good working order. The apparatus itself must not depreciate and the efficiency of the A and B battery power supply must be maintained. If batteries are used as a source of power they should be inspected regularly. If storage cells are to be used, a suitable number of the 8-amp.-hr. miners' cap-lamp batteries would give satisfactory service. In special cases dry cells may be used. Present tests indicate that a properly designed hand-cranked generator, designed to supply a 6-volt filament current and a 250-volt plate current and provided with a suitable filtering system, will prove satisfactory for underground transmission and reception.

4. The receiving apparatus should be simple to operate and probably should be very sensitive, for in practically all types of underground communication, whether by direct ground, induction currents, radio, and to a much less extent line-radio, much of the energy is absorbed.

WEIGHT AND SHAPE ARE MOST IMPORTANT FACTORS

5. The last and probably the most important point to be considered is the weight and shape of the signal apparatus. The equipment should be light or it will not be sufficiently portable for underground use. It is possible that a satisfactory arrangement may be designed so that the transmitting and receiving apparatus can be placed in one cabinet, and the power supply, whether batteries or hand-cranked generator, can be carried in another. A suitable non-reversible plug, safe in atmospheres containing explosive mixtures of methane and air could be used for connecting the power supply to the apparatus when in use. The general shape of case and carrying straps or handles must be such as to allow the apparatus to be readily moved while underground should it be necessary to crawl or keep one hand free.

Methods being Investigated—The present investigation being conducted includes the (1) T.P.S. or ground-conduction methods; (2) induction signaling with both high and low frequencies; (3) line-radio over underground mine power and telephone lines, trolley wires, rails, and through piping for water and compressed air; (4) radio; and (5) electrical geophones and auxiliary equipment. These investigations include studies of the effects of earth falls, mine floods, and similar conditions encountered during disaster, as well as general underground conditions existing in the ordinary operations of metal and coal mines.

UNDERGROUND CONDITIONS MAY DETERMINE TYPE

A practical type of apparatus to be of use to the mining industry should be capable of operating over distances of from 500 to 3,000 ft. or more underground through different strata—coal, orebodies, etc. It is probable that apparatus suitable for one geologic condition may not be so satisfactory for another.

The ground conduction system—Because of its simplicity, and also to facilitate obtaining certain fundamental data regarding underground transmission, the T.P.S. set used and developed by the Signal Corps of the

U. S. Army was first subjected to experimental test. This report is the first of a series dealing with electrical methods of underground communication and signaling, and is confined solely to the results obtained with the T.P.S. set.

The T.P.S. method, or ground telegraphy, is a means of communication which requires no wire connection between the sending and receiving stations. It differs from radio telegraphy in that the transfer of electrical energy from the transmitting to the receiving apparatus is through the ground and more by conduction than by induction, whereas with radio the transmission is through the air. The current generated by the transmitting apparatus is a variable alternating current of comparatively low frequency, such as 0.5 to 1.8 kilocycles per second, instead of the high-frequency oscillations of 100 to 3,000 kilocycles per second, which are commonly employed for radio communication.

Description of apparatus used—The apparatus used in these investigations consisted of the standard U. S. Army Signal Corps T.P.S. set, box type BC 21, weighing 40 lb. The transmitting set consists of a power buzzer or buzzer transformer which generates a high-voltage audio-frequency alternating or variable electromotive force of unsymmetrical form; a storage battery for supplying power to the primary circuit of the power transformer and the filament of the receiving tubes; a telegraphic key for interrupting the power supply in order to transmit code signals; and the necessary ground equipment consisting of ground stakes, field wire, etc.

The power buzzer or transformer, shown in the diagram of connections in Fig. 1, is practically the same as the old French T.P.S. buzzer set. The transformer consists of a laminated rectangular iron core of special shape with two windings—primary and secondary. Connected in series with the primary winding of the transformer is the power supply, a telegraphic sending key and an interrupter vibrator of special design. When the sending key is depressed, the primary circuit is closed, and the current flow in the primary coil magnetizes the core and draws the vibrator downward.

The circuit is then broken at the vibrator contacts, and the magnetic field decays, the vibrator again returning to its first position, the action being analogous to the familiar induction coil used for ignition in many automobiles and gas engines. A pulsating current is thus made to flow in the primary circuit. The secondary high-voltage winding of the transformer is wound directly over the primary. The pulsating direct current flowing in the primary winding induces a high-voltage variable electromotive force in the secondary winding which, when the secondary circuit is closed, causes a variable alternating current of the same frequency to flow in the secondary or ground circuit.

T.P.S. SYSTEM FOR TELEGRAPHIC SIGNALS

By properly opening and closing the key telegraphic signals may be transmitted. The T.P.S. method of signaling is for telegraphy only and cannot be used for voice or speech transmission. The frequency of the pulsating current depends upon the adjustment of the vibrator and may be varied between frequencies of approximately 500 to 1,500 cycles per second by means of a set of small weights fastened, singly or in pairs, to the vibrator armature.

The magnetic circuit of the power transformer is a closed iron core, except for a V-shaped air-gap between

the iron core and the iron armature attached to the vibrator. This is shown schematically in Fig. 1. A 6-microfarad condenser is shunted across the vibrator contacts to reduce sparking and to give a greater time rate of change of primary current at the instant the circuit is broken by the vibrator.

A switch is provided for changing over from transmitting to receiving. On the receiving position the switch disconnects the transmitting power supply and

Fig. 3—Signal Strength Decreases When Ground Connections of Outfits Are Not Parallel

Regardless of the conductivity of the soil the relative audibility of the signals decreases as the angle between the base lines of the sending and receiving sets is increased. Normal damp soil permits an easy flow of current into the earth; loose, dry, sandy soil offers high resistance; whereas snow-covered soil short-circuits the two ground connections of the sending outfit and the earth currents fail to penetrate to any practical degree.

the secondary of the transformer from the ground wires, and connects the primary of the first audio-frequency amplifying transformer directly across the ground terminals. On the transmitting position the receiving apparatus is disconnected from the ground terminals and the filament circuit of the tubes opened.

The receiving equipment is practically the same as the ordinary two-step transformer-coupled cascade amplifier used for audio-frequency amplification in radio telephone and telegraphic work. The cascaded method consists of a series of amplifying tubes arranged electrically so that the amplified output of each tube is received by the next tube, where still further amplification takes place. Each tube with its auxiliary coupling apparatus is called a stage or step of amplification.

The secondary of the first transformer is connected between the filament and grid of the first vacuum tube. The plate circuit of this tube is connected in series with the primary of the second transformer, which couples the grid circuit of the second tube. The phones are placed in the plate circuit of the second tube. A 45-volt B battery furnishes the plate voltage for the tubes. The filaments of the two vacuum tubes are connected in series with a rheostat for regulating filament current.

Fig. 4—Regardless of the Kind of Earth, Signals Become Fainter with Increased Distance

At short distances from the transmitting station the audibility was high but rapidly became lower as the distance was increased. It will be noticed from the curves that the rapid decrease in audibility was not uniform; there was a point on each curve where the signals faded out slowly.

The principle of operation of the T.P.S. method of signaling is very simple. The secondary terminals of the power buzzer are each connected to an insulated ground wire connected to the ground. The two ground terminals are placed from 50 to 1,000 ft. apart, the distance depending upon the communicating distance and the local topographic and geologic conditions. The high-voltage secondary current from the transformer flows through the ground wire to its grounded end, through the earth to the grounded end of the other ground wire and back to the transformer.

The current flowing between the two ground terminals does not confine itself to the straight line connecting the two terminals, but spreads out somewhat in the form of a sphere when the terminals are at a sufficient distance underground; and somewhat in the form of a hemisphere when the terminals are placed on the surface of the earth. The distribution of current about the line joining the two ground terminals depends largely upon the relative conductivity of the different strata and earths between the terminals.

The lower the resistance the greater the current flow through that particular strata or conducting strip. Advantage is taken of this fact in order to pick up the currents. For receiving T.P.S. signals, two ground terminals, similar to those used in transmitting, are connected by means of low resistance insulated wires to the input of the receiving apparatus. The current flow through the ground in the vicinity of the receiving station, flows through the circuit composed of the ground leads and the receiving set.

If it is desired to both send and receive at a station, the same ground terminals are used and a change over switch used for connecting either the transmitting or

receiving apparatus to the ground terminals. For ordinary use, where communicating distances from 500 to 1,000 ft. are to be covered, the ground connections should be not less than 100 to 200 ft. apart, and a sensitive two-step audio-frequency amplifier used for receiving.

For reliable underground communication it has been found that this method of signaling is effective only for a distance equal to from two to four times that at which the ground terminals are placed. If, for instance, the terminals at each station are placed 200 ft. apart and the lines joining them are approximately parallel, signals can be reliably transmitted a distance of from 400 to 800 ft. In many cases this range is greatly exceeded, depending on local topographic conditions and on the degree with which leakage and induction currents from power and trolley wires in the mine and on the surface interfere with transmission of the signaling current.

NON-CONDUCTING EARTH PREVENTS PENETRATION

Factors affecting transmission of signals—In the horizontal transmission of signals along the surface of the earth natural surface conditions affect the range considerably. A stratum of non-conducting earth immediately below the transmitting set will prevent the current from passing to any great depth and usually will force it to spread out horizontally to fairly considerable distances. A very dry earth surface, being of high resistance, or a high-resistant connection at the ground terminals will permit only a weak current to flow between the terminals, and usually reduces considerably the distance over which communication is possible.

On the other hand, a very wet surface usually provides too good a conductor, and permits practically all the current to flow directly between the ground connections without spreading out. If a transmitting set is placed close to a river or other place where the subsoil is very wet, the range of the apparatus will usually be less. Conductors buried in the earth or in contact with and lying on the surface, such as metallic piping for water, compressed air, drainage, and sewage, railroad tracks, etc., also greatly reduce the transmitting range of the set, and care must be taken that the ground terminals are placed as far as possible from such metallic conductors, which short-circuit the ground return currents and prevent their spreading or penetration. Under suitable geologic conditions the lines by which current flows between the grounds may spread out as far as two or possibly even three miles from the sending station.

As a preliminary study in the use of T.P.S. sets, the characteristics of the sets for horizontal transmission along the surface of the ground were first determined, and the curves indicate some of these characteristics. Tests were made in different localities, and although the general curves cannot be locally applied quantitatively, they are of value in indicating the general characteristics of the set.

SNOW AND RAINS REDUCE RANGE OF SIGNALS

For any given installation, the signal range varies with local rains, surface and drainage, etc. As a rule, small showers, after a short interval to allow surface drainage, do not appreciably affect the range; but during heavy rains or when the snow is melting there is usually a marked decrease in the range of transmission. The latter factor has, however, not always been

found to hold true when the two ground connections are placed on the opposite sides of a water shed, such as when the T.P.S. set is placed on the ridge of a hill and the two ground leads extended outward a sufficient distance on opposite slopes of the ridge.

The curves in Fig. 2 were obtained by varying the distance between both the transmitting and the receiving ground terminals and keeping parallel the two base lines of the transmitting and receiving sets with the distance between stations constant. For these tests two-step audio-frequency amplifiers were used, with an audibility meter shunted across the phones. The curves indicate that the transmission and receiving ranges of the set vary almost directly with the distance between their respective ground terminals. The greater the distance between terminals the greater the range.

When the sets are used underground, an effort should be made to make the distance between terminals as great as possible. Should it be necessary to place the grounds in an entry or drift containing car tracks, compressed-air piping, or other conductors, maximum range will usually be obtained only if special care be taken to keep the ground terminals as far as possible from such conductors.

In Fig. 3 is given the relationship between the audibility of the received signals and the angles between the base lines of the two sets. It will be noted that for the most audible signals the two base lines should be parallel. As the angle between base lines approaches a right angle, the signal strength or audibility decreases abruptly, although the audibility varies considerably with surface conditions. Even at right angles, however, the signal strength did not drop to zero.

In Fig. 4 is shown the relationship of the distance between stations and the audibility of the receiving signals. The stations were placed with their base lines parallel, and both receiving and transmitting ground terminals were kept 200 ft. apart. It will be noted that the audibility drops off rapidly with the first few hundred feet, but after that it decreases slowly with the increased distance between stations. At distances around 1,000 ft. good readable signals were obtained.

Transmission along mine tracks—Compressed-air piping, car rails, or other conductors may be used as a carrier for T.P.S. signals. Little difficulty was experienced in transmitting signals over such conductors in any part of the Bureau's experimental mine. The decrease in relative audibility of signals with the distance between stations is similar to that for transmission on the surface, shown in Fig. 4. In this series of tests the tracks were, in a number of places, covered with mud and water, and were laid directly upon the mine floor. In two places 8-in. wooden rails had been inserted as a protection against lightning, but the T.P.S. current penetrated the wooden rails—which were wet—without any great decrease in audibility.

In order to determine the effects of mine cars upon the track, a mule was hitched to two pit-cars and a truck. The transmitting set was at the rear of the mine, about 1,200 ft. from the entry where the receiving set was placed. The curve in Fig. 5 indicates the relative audibility of the received signals as the mine cars were moved from the entry toward the interior of the mine. It is interesting to note that the audibility is low when the mine cars are near either the transmitting or receiving sets, but as the distance between the transmitting or receiving set and the cars is increased, the audibility rises considerably. The effects

of short-circuits upon tracks are particularly noticeable in rail radio.

Similar tests were made at the Pittsburgh Terminal Coal Co. Mine No. 3 and the mine of the Inland Collieries, Inc. In the first mine an unused portion of track with 20-lb. rails which was covered with heavy roof falls, mud and water nearly its entire length was used during one test. The rail joints were broken in many places and heavy rust covered all metal joints; fishplates, switches, etc. This series of tests indicated clearly the carrying power of T.P.S. signals over poor conductors running through water, coal and mud covering.

Additional tests at the Inland Collieries, Inc., mine are of particular interest, and illustrate a rather peculiar phenomenon. These tests were conducted on one of the main haulageways. Thirty-pound rails are used, all joints securely copper bonded and the rails cross-bonded every 150 ft. with heavy copper leads. The transmitting set was connected to the rails at the point where one of the cross-bonds connected or short-circuited the two rails.

The receiving set was mounted upon a storage-battery locomotive and two short leads with spring clips used for making contact with the rails. Signals could be read at distances from the transmitting set 1,900 ft.

Fig. 5—How Signal Device Operated When Transmission Was Through Rails

The trip of cars seemed to act as a shield or absorbent whenever it was near either the sending or receiving station. It will be noticed that the signals were strongest when the trip of cars was about equidistant from the transmitter and receiver.

away. The low-frequency and commutator hum from leakage and induction currents from power and trolley wires drowned out the signals at distances greater than 1,900 ft. No explanation is being advanced at this time as to how or why the signals traveled along the short-circuited and cross-bonded rails. The curves of Fig. 6 show graphically the relation between signal audibility and rail transmission distance.

VERTICAL COMMUNICATION PROVED SUCCESSFUL

Vertical Transmission—In the tests conducted at the Bureau's Experimental Mine, the T.P.S. set was placed in the mine 600 ft. from the entry. Ground leads extending 100 ft. from the set were used, one lead going to ground 500 ft. from the entry and the other lead placed 700 ft. from the entry. Because of the narrowness of the entry the ground plates were laid upon the mine floor within 3 ft. of the car rails. The grounds consisted of 22-gage galvanized iron plates 6x36 in. connected to each ground lead. The connection was made to the plates by means of two battery clips.

The plates were placed on the moist mine floor, and, after sliding and pressing to give good contact, lumps of coal were placed on the plates. For mine use, iron stakes or pins, as used during the surface investigations, would in some instances be impractical. It is usually difficult to drive a peg into coal or shale strata, and such grounds are often poor electrically because of the small surface contact in friable material such as coal. A coal wedge can, however, be driven into coal.

The receiving set was placed on the surface as nearly over the T.P.S. set as could be estimated. The first reading was taken with the receiving set above the mine set. The receiving set was then moved 100 ft.

west and readings taken. Repeated readings taken every 100 ft. showed the gradual decrease in audibility of the signals. Little difficulty was encountered in transmitting signals obliquely through a distance of about 800 ft. of rock.

Similar vertical transmission tests were carried out at the Pittsburgh Terminal Coal Co.'s mine No. 3. This mine is opened by a shaft about 250 ft. deep. Signals were transmitted without much difficulty from the mine to the surface. A heavy rain fell during the first part of these tests and the receiving apparatus was not removed from the automobile. Two 100-ft. ground leads were run in opposite directions to the side of the road, and code messages easily were received from the mine. The heavy rain, and water covering the road, did not prevent the set from working.

SURFACE AND UNDERGROUND TERMINALS PARALLEL

During the second day of the tests, the ground was covered with about 3 in. of snow, and as before, code messages readily could be received. These tests were made with the surface ground terminals approximately parallel to those underground. Later tests, where the terminals were placed approximately at right angles, showed a marked decrease in signal strength-interference ratio indicating as had been found in the tests at the Experimental Mine, that the two ground terminals should be approximately parallel for maximum signal strength and a minimum of interference from low-frequency leakage currents. If the general direction of the underground terminals is not known when setting up the surface station, two ground lines at right angles to each other are run; thereby giving a maximum angle of 45 deg. between sending and receiving terminals. The signal strength is not greatly reduced by a 45-deg. angle.

Underground Tests in Illinois Mines—Additional T.P.S. data are being obtained from tests now in progress in Illinois coal mines by A. B. McCall, assisted by members of the Springfield Radio Club. The data obtained will deal largely with the results in the deep coal mines near Springfield, Ill.

The tests conducted on the T.P.S. method of signaling indicate the following: (1) The apparatus is extremely simple, reliable and foolproof. (2) The method should not be considered as a general solution of the problem of underground communication because with it only the telegraphic code can be used. (3) Reliable communication can be established through the earth a distance of only two to four times the distance between ground terminals. To transmit the energy 800 ft. through the earth requires, as a rule, ground terminals on both transmitting and receiving sets separated from 200 to 400 ft. (4) The signalling tests made with the T.P.S. set using untuned audio-frequency ground-conduction currents indicate that stray and leakage currents flowing through the ground may greatly interfere with the transmission of signals. Weak signals may be entirely lost as a result of the interference. On the surface such interference may sometimes be minimized by placing the ground leads at right angles to power lines, etc., but underground the ground terminals cannot be thus placed. (5) Present data indicate that the most feasible way of eliminating low-frequency interference is to employ loosely-coupled tuned high-frequency circuits, these being more successful than low-frequency filter circuits.

Fig. 6—Records Show Advantage of Using Bonded Mine Rails

Conduction through materials of low resistance was much greater than through high resistant material. Intervening bodies of water, pipe lines, etc., take the earth currents in other directions than those upon which the operation of the equipment depends.

Illinois Coal Corporation Is Building Huge Mine Despite Adverse Economic Conditions

ONE of the baby giants among the huge coal producers of the country is the Nason mine of the Illinois Coal Corporation. This operation is now in the development stage at the new town of Nason, Jefferson County, Illinois. It is eventually expected to attain a capacity of at least 10,000 tons a day and will be equipped to hoist coal from either or both of its two shafts. The bottom, which is now in process of construction, will be so designed that hoisting can be shifted quickly from the main shaft to the airshaft in case of necessity. The mine is surrounded by the lines of the Burlington, the Chicago & Eastern Illinois and the Wabash, Chester and Western Railways, but it nevertheless lies several miles away from a railroad.

Consequently the coal corporation has built an 11-mile line of its own. This is known as the Jefferson Southwestern and extends from Mt. Vernon southwest to the town near the mine site. The owners have not yet secured permission for full operation of the line. A passenger car, driven by gasoline, however, is in service between Mt. Vernon and Nason. It forms at present the only railroad service for this latter community which already has a population of about 800. The town may be incorporated as a city as soon as it has 1,000 residents.

The Illinois Coal Corporation holds coal rights to about 30,000 acres of land in the region of Nason. This is underlaid with the No. 6 bed of Illinois coal

Building the Wash House

Wash houses are legal requirements at Illinois mines. As may be seen this one will be large, modern and commodious. The town of Nason, which can hardly be termed a mushroom community, may be seen spreading over the townsite in the left background of this picture.

Foundation Building

The concrete stack, 10 ft. in inside diameter and 200 ft. high has been completed, and the boiler- and engine-house foundations as well as those for the equipment they are to house are shown in the final stages of completion. Power for operation of the mine as well as for town lighting will be generated at this station. The temporary headframe above the air shaft may be seen in the rear ground. About 300 tons of coal already are being hoisted from this shaft daily.

Gasoline Passenger Car

Full rights to operate the Jefferson Southwestern Railway have not yet been obtained. This car, driven by a gasoline engine, at present forms the only means of railway communication so far as passengers are concerned between the town of Nason and the outside world.

which at this point is about 8 ft. 6 in. thick and 720 ft. below the surface. The new mine is only a few miles north of the well-known Franklin County field, famous the world over for its group of huge operations including the Orient and Zeigler properties—the largest in the world. The plan is to make this operation as independent as possible. The mine and town will be served with power and lighting current from a power plant to contain three generating units, one of 500 kw. and two of 1,000 kw. capacity each. The three turbine

Flame Caps Have Been Used for Testing Gas for Over a Hundred Years

UP TO DATE the earliest account of a method for detecting the presence of firedamp in coal mines appears in a letter dated Oct. 18, 1813, from John Buddle to the "Society in Sunderland for Preventing Accidents in Coal Mines," wherein the utilization of the "cap" or aureole which forms around a flame burning in an atmosphere containing inflammable gas is described. The following is an extract from this letter:

"The common pit candles vary in size, but those generally used are forty-five to the pound; the wick is of cotton, and the candle made of ox or sheep tallow; but clean ox tallow is the best.

"The mode of trying the candle, as it is called, to ascertain the mixture of inflammable gas, is as follows:

"In the first place, the candle, called by the colliers the "low," is trimmed, that is, the liquid fat is wiped off, the wick snuffed short, and carefully cleaned of red embers, so that the flame may burn as purely as possible.

"The candle being thus prepared, is holden between the fingers and thumb of the one hand, and the palm of the other hand is placed between the eye of the observer and the flame, so that nothing but the spire of the flame can be seen, as it gradually towers above the upper margin of the hand. The observation is generally commenced near the floor of the mine, and the light and hand are gently raised upwards, till the true state of the circulating current be ascertained.

"The first indication of the presence of inflammable air is a slight tinge of blue or bluish grey color shooting up from the top of the spire of the candle, and terminating in a fine extended point. This spire increases in size, and receives a deeper tinge of blue as it rises through an increased proportion of inflammable gas, till it reaches the firing point; but the experienced collier knows accurately enough all the gradations of 'shew' (as it is called) upon the candle, and is very rarely fired upon, excepting in cases of sudden discharges of inflammable gas."

The earliest reference to this method of testing

sets will be driven by steam from four 481-hp. water-tube boilers installed in a brick and steel power house.

The job of sinking the two Nason shafts, which lie 525 ft. apart, was a record breaker in point of speed. Actual construction was started April 23, 1923, and the shafts were completed in November and December of the same year. The "A" shaft, which is the main opening, is 12 ft. 5 in. x 21 ft. 5 in. in cross section and was sunk at an average speed of 8 ft. per day. The "B" shaft, 12 ft. 5 in. x 31 ft. 5 in. was sunk at an average of 5 ft. per day. At each shaft three crews kept the work moving every hour of the day. Six weeks was lost when the sinkers encountered between 12 and 15 ft. of quicksand 70 ft. below the surface. This had to be closed off with sheet piling. The shafts are timbered and gunnited to render them fireproof. Each is divided into three compartments. The "A" shaft has two hoisting compartments each 8 x 12 ft. 5 in. and one stairway compartment 4 ft. x 12 ft. 5 in. The larger shaft has an air compartment 14 ft. x 12 ft. 5 in. Development of the mine is proceeding rapidly from the bottom of these shafts, about 300 tons of coal being hoisted daily from the air shaft alone.

appears to be that contained in "The Life of the Right Hon. Francis North," by Roger North, published in 1742, where an account is given of a visit paid in 1676 to coal mines in the Newcastle district. In a description of "damps or foul air," the author states that "an infallible test is by a dog; and the candles show it. . . . The flame of a candle will not kindle them so soon as the snuff."

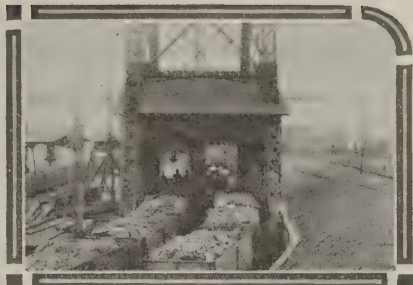

Gases Caused by Detonation of Powder

A study of the products of the detonation of explosives has been undertaken at the Pittsburgh Experiment Station of the Bureau of Mines. Sampling equipment has been installed for obtaining nine simultaneous samples of the product arising from the combustion of explosives when shot under actual coal-mining conditions. The sampling device is to be used: (1) to determine whether the powder fumes concentrate at the top, bottom, or sides of the working place when liberated by different kinds of shots; (2) to take crevice samples of the concentrated fumes whenever possible, fine capillary tubes being inserted for this purpose into the crevices of the coal from which samples will be taken into evacuated gas-sample tubes, so that the carbon dioxide and carbon monoxide ratios in these samples may be compared with the ratios obtained in testing by the Bichel gage; (3) to take samples of the fumes at a point 4 ft. from the face and in the middle of the place, one, three and five minutes after shooting to determine what concentration of carbon monoxide is in the atmosphere at that point. These data should determine how soon a workman should be allowed to return to the face after he has fired a shot.

Samples of gases from the Bichel gage and of the atmosphere in the mine after a shot has been fired have been taken and analyzed to determine the percentages of oxides of nitrogen. So far these analyses have showed that the quantity of these deleterious gases in the resulting atmosphere do not exceed 0.002 per cent. These tests will be continued until the gases from many different explosives have been examined.

News Of the Industry

Senator Oddie Prepares to Introduce His Coal Measure

Embodies Portion of Proposal for Department of Mines—All Branches of Coal Industry Consulted in Formulation—Statistical Data Sought on Voluntary Basis, Reports to Be Confidential

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

AFTER having given careful consideration to the oral argument made before him by Messrs. Brydon, Cunningham and Gandy, officials of the National Coal Association, Senator Oddie, chairman of the Senate Committee on Mines and Mining, has decided that it is not in the public interest to withhold his coal bill, as they request.

While it was Senator Oddie's idea early in this session of Congress to introduce his coal bill promptly, developments were such that the need for haste passed. On learning that the Pinchot bill was not to be pressed and on the signing of the Jacksonville agreement, he felt that all the time necessary to the perfection of the measure might well be taken. Certain sections of the bill, which is a portion of his Department of Mines proposal, still are under consideration. In fact, the entire measure is subject to revision. All branches of the industry have been consulted during the formulation of the legislation.

Follows Garfield Proposal

Senator Oddie has attempted to carry into effect one of the recommendations made by Dr. Harry A. Garfield at the close of his service as Fuel Administrator. That section of the bill in its present form reads as follows:

"That the Secretary of Mines is hereby authorized and directed to provide for the organization of two advisory committees, each composed of three representatives of the producers of coal, three representatives of the consumers of coal, three representatives of the coal miners and three representatives of the transportation agencies. Said representatives of transportation agencies shall be invited to sit on said advisory committees only when the subject of the transportation of coal is under discussion, and shall not participate therein when the subject of labor relations in the coal industry is under consideration.

"The said representatives shall be selected by said Secretary from names of persons furnished by the several interests represented, and shall be appointed by the President, upon the recommendation of said Secretary. The

first of said committees shall be known as the Bituminous Coal Advisory Committee and shall advise said Secretary with respect to all matters related to and affecting the bituminous-coal mining industry and the second of said committees shall be known as the Anthracite Coal Advisory Committee, and shall advise said Secretary with respect to all matters related and affecting the anthracite-coal mining industry. Meetings of said committees shall be held, in the District of Columbia and elsewhere in the United States, as frequently as may be necessary for a thorough consideration and discussion of all matters and problems affecting all branches of the coal industry and its relations to the consuming public.

"Said Secretary shall be chairman ex-officio of said committees. He may, in his discretion, invite or request the attendance of persons not members of the advisory committees herein provided for and he may organize advisory committees of the wholesale and retail coal trade and invite or request their attendance at meetings.

"All plans for the collection of information shall be submitted to the advisory committees for their criticisms and recommendations, both as to the nature and scope of the information to be collected and as to the method of collection, analysis and presentation, but in case of disagreement the decision of the Secretary of Mines upon these points shall be final."

Seeks Voluntary Statistics

It is Senator Oddie's idea that statistical information as to coal is to be submitted on a voluntary basis, with provision, however, for the government to check any returns which may be regarded as of questionable accuracy. "Such reports," reads the draft of the bill, "shall be held confidential to the extent that no part thereof shall be divulged or published in such manner as to specifically identify such report or information with the name of the owner, operator, dealer or person providing the same; to that end for the purpose of obtaining accurate and complete information from all owners,

"Sheriff Alex Howat"! How Does That Sound?

The hundreds of coal miners loyal to Alex Howat in Kansas are trying their best to make it possible for Alex to collect a living wage from somewhere. Balked by International President Lewis in their recent attempt at the Kansas convention to get considerable back union pay for Alex for the period between the time Lewis fired him for calling an unauthorized strike and the time his normal term of district president ran out, they are now booming him for Sheriff of Crawford County, Kansas. They are not particular about the ticket he runs on. Alex's previous relation with the sheriffship of Crawford County was that of prisoner behind the bars.

operators, dealers or persons reporting and to insure the inviolability of such business facts as, if known to a competitor or others, would injure, or tend to injure, the business of the owner, operator, dealer or person so reporting, an officer shall be designated to receive and act as custodian of said reports.

Report to Be Confidential

"Said custodian shall be responsible for providing and carrying out an effective plan to prevent the accidental or unauthorized identification with its source of the information furnished in said report. For this purpose and in connection therewith the following, or some equally effective procedure shall be observed: Said custodian shall provide a report blank, so perforated as to permit its division into two parts. The upper portion shall be designed to permit the entering of the name and address of any owner, operator, dealer or person. The lower portion shall contain suitable space for the entering of the material of the report.

"Said custodian shall also provide envelopes, or other suitable mailing device, bearing the frank of the Department of Mines, the use of which is hereby authorized by owners, operators, dealers and persons in sending their reports to said custodian. The word 'confidential' in boldface type shall be printed on said envelope or suitable mailing device. All such envelopes containing the reports above mentioned shall be opened only by said custodian or by a responsible person or persons designated by him to perform such duty."

Machine Mining Gaining In West Virginia

During the fiscal year ended June 30, 1923, there were 3,954 mining machines in use at 1,208 mines in West Virginia employing 49,425 men and producing 65,304,874 gross tons of coal, which is 75.04 per cent of the total production of the state and 10,845,347 gross tons more than was mined by machine during the fiscal year ended June 30, 1922. Since 1897 the volume of machine coal has grown from 5.12 per cent of the total to 74.86 per cent of the total and the number of machines in use from 55 to 3,954.

Railroads Refuse to Join Coal Export Committee

F. R. Wadleigh, formerly Federal Fuel Distributor and head of the Commerce Department's coal division, is trying to organize a committee of coal exporters and representatives of the railroads. The coal exporters approved the plan. The carriers, however, have declined definitely to co-operate in the formation of the committee. Mr. Wadleigh has received the following letter from Robert M. Collyer, chairman of the Trunk Line Association Traffic Executive Committee:

"Subsequent to my letter of March 8, the necessity developed on short notice for a meeting of traffic executives of Eastern roads without opportunity for arranging a conference with you. The question of appointing a committee to meet with you to discuss the suggested formation of an Export Coal Committee was considered, however, and it was thought that no helpful result would come from the representation of railroad traffic officers on such a committee.

"The railroad officers specializing in coal traffic make a constant study of this great movement in all its phases—local, coastwise, and export—and as applied to railroad transportation it is believed that its problems are thoroughly understood.

"You will appreciate that if the railroads in their public-service capacity should associate themselves in an export association for one commodity they could scarcely withhold joining with all comers—an added liability that they would not wish to have attached to their already great burden in co-operating with the shippers in rate matters.

"We believe that our coal shippers understand that the Eastern railroads will be glad to receive any questions that the coal exporters may desire to have considered."

8,000 Alberta Miners Strike

Eight thousand miners in the coal fields of Alberta and eastern British Columbia (District No. 18) went on strike April 1.

The men demanded a three-year agreement in line with one adopted at Jacksonville and recently ratified by the union. Refusing this, the operators offered renewal for one year of the present contract, but without the war bonus of \$1.17 a day.

Henry Walker

The genial deputy chief of the Mines Department of Great Britain who, with Dr. R. V. Wheeler, director of the Experimental Mine of the Mines Department, has been visiting the U. S. Bureau of Mines and the mines of this country and incidentally addressing crowds of interested coal men.

How Strike of 1922 Affected Working Forces

How the strike of bituminous-coal miners in 1922 curtailed the productive capacity of various districts is shown in a table just issued by the U. S. Geological Survey. The figures represent the per cent of miners absent from work, based on the weekly reports of production and running time furnished by about 3,000 mines, supplemented by

Hoover Appointed Head of Transportation Committee

A meeting of President Coolidge's committee to study ways and means of co-ordinating rail and water transportation was held at the White House April 3, when plans were mapped out for a comprehensive study of the problem. The President named Secretary of Commerce Hoover as chairman of the committee, which includes the chairman of the Shipping Board, the president of the Fleet Corporation, the chairman of the Interstate Commerce Commission; Daniel Willard, president of the Baltimore & Ohio R.R., and A. G. Smith, president of the American Steamship Owners' Association.

The committee will seek some method of improving the system of handling freight destined for export between terminals, and other steps by which greater co-operation between rail and water lines may result. Chairman Hoover expects to consult with Senator Jones, chairman of the Senate Committee on Commerce, who suggested the study as a step in the direction of assisting the American Merchant Marine.

the annual reports of numbers of men on strike and total numbers employed. The percentage of district capacity closed during the strike varied from zero in the Logan, Hazard, Harlan and Alabama districts, less than one-half of 1 per cent in Kenova-Thacker and Pocahontas and Tug River to 92 per cent in central Pennsylvania, 95 per cent in the Pittsburgh district and 100 per cent in Illinois, Indiana and southern Ohio.

Loss of District Capacity Caused by 1922 Strike

District	Maximum Per Cent of District Capacity Closed During 1922 Strike	District Production in 1918	Tonnage Loss (Product of Columns 1 & 2)

Average.....	73.3 (g)	579,281,000	425,355,000

(a) Partly estimated. (b) Less than half of one per cent. (c) Certain stripping pits and mines serving purely local trade continued to operate. (d) Includes all of northern West Virginia except the Panhandle and Cumberland-Piedmont districts. (e) Includes all high-volatile coal produced in southern West Virginia except that in the New River, Logan, and Kenova-Thacker districts. (f) Includes Tennessee and all of southeastern Kentucky except Harlan County. (g) Because the moment of maximum effectiveness did not come in all districts at the same time the shutdown over the country as a whole was never quite as great as is here indicated.

Music Hall at Cincinnati, Ohio, Where Coal-Mining Exposition and Convention Will Meet May 12-17, 1924

Here operators, executives and engineers will discuss the vital subjects relating to mine operation and have an opportunity of acquainting themselves with the most up-to-date equipment for expediting the extraction of coal and lowering the costs of pro-

duction. Opportunities of this character are not frequently presented and once a year is none too often to take a glimpse of the new facilities for lightening the labor cost of production, which is this year of more vital importance than ever.

Pineville Mine Resumes Under the Protection of Machine Guns and Infantry

Special Dispatch to Coal Age

Louisville, Ky., April 7.—The Liberty Coal & Coke Co., on Straight Creek, Pineville, Ky., resumed operations this morning, with thirty-five men, with the camp protected by two companies of national guardsmen, one a machine gun company of sixty men, and the other an infantry company of the same number, the troops having arrived on Sunday.

Governor Fields and state military officials had quietly sent the troops on advice of the sheriff at Pineville. It was reported that shots were exchanged this morning under cover of darkness at about 2 o'clock, prowlers having been discovered near the power plant. It is reported that the valley is now protected by machine-gun nests on the hillsides and patrols of infantry. The miners are working today, all men being armed.

Company officials reported that they were willing to confer with Governor Fields relative to the situation, but would not arbitrate with former union employees, who had left the company employment.

They Shoot Non-Union Men Down in Kentucky

Two non-union miners were shot and one of them killed by mountainside riflemen near Pineville, Ky., April 3. They were employees of the Liberty Coal &

Jobs For Jobless Miners

The United Mine Workers Journal, official union publication, recognizing that many union miners must leave the industry, announces that Secretary of Labor Davis will "place the entire resources of the Department of Labor at the command of mine workers who wish to obtain employment in other industries." The director of the Federal Employment Bureau of the department receives applications and tries to find the jobs. The *Journal* quotes Secretary Davis as saying: "There is no need of men now employed in mines working short time, because there is plenty of opportunity for steady work in other industries."

Coke Co. on Straight Creek. This company recently reopened its property on the 1917 wage scale and evicted from company houses all miners who did not go back to work. Last November the company asked its miners to decide between working at the 1917 scale and shutdown of the mines. The question went to an arbitration board, which never has reported. After a period of shutdown the company decided to operate on the 1917 basis of wages and invited its union men to remain on that basis if they wanted to. Some did. Non-union men were brought in from Virginia and elsewhere and finally some evictions of union men who refused to work were made. Then the shooting began.

Yukon Blast Unofficially Laid To Open Lamp in Gas Pocket

The explosion at No. 2 mine of the Yukon-Pocahontas Coal Co., on March 28, which took a toll of 24 lives, was caused by the flame from a miner's lamp when a gas pocket was encountered, according to an unofficial opinion following a preliminary inspection by R. M. Lambie, chief of the State Department of Mines. More complete investigation seems to indicate that when the second trip was wrecked those who remained behind to help replace the motor on the track escaped and that those who went forward met death when they encountered the gas pocket.

West Kentucky Still Wobbles On Wage Problem

No settlement is yet in sight between the union and the operators in western Kentucky—or that part of western Kentucky whose contract was extended from April 1 to April 15 to permit a possible new agreement. Meantime the impression is spreading fast that no contract will be signed and that the whole territory will be non-union by summer.

In Henderson County, in the northern edge of the western Kentucky field, where a sort of agreement with the union ran out April 1, no new agreement has been made and the region with its ten mines is now on a non-union basis.

Fewer Coal-Mine Fatalities
In February

The fatal-accident rate for coal mines during February, 1924, showed a gratifying reduction as compared with the preceding month and with February, 1923, according to reports received from state mine inspectors by the Bureau of Mines. For each million tons of coal produced the death rate was 2.69 as compared with 3.94 in the previous month and 6.07 for February last year. For bituminous mines alone, the rate for February, 1924, was 2.32, as compared with 6 for February, 1923; for anthracite mines the rate was 5.05 as against 6.43.

The actual number of fatalities reported during February was 138, of which 118 occurred at bituminous mines and 40 at anthracite mines. In February last year the number of fatalities was 303, of which 253 were at bituminous mines and 50 at anthracite mines. The 303 fatal accidents in February, 1923, include the loss of 120 lives in an explosion at Dawson, N. M.; during February, 1924, no single disaster killed as many as five men.

The record for the first two months of 1924 shows a production of 112,071,000 tons of coal, 461 lives lost, and a fatality rate of 4.11 per million tons, the bituminous rate being 3.84 and the anthracite rate 5.79. For the corresponding months of 1923 the output of coal was 108,824,000 tons, the number of deaths was 509 and the fatality rate was 4.68, the bituminous rate being 4.49 and the anthracite 5.70. Thus the fatality rate for January and February of the present year is about 12 per

Van H. Manning

Formerly director of the U. S. Bureau of Mines, Mr. Manning has been for several years director of the division of research of the American Petroleum Institute, from which he resigned recently. Since March 10 he has been with the Pan-American Petroleum & Transport Co., with headquarters in New York City.

cent below that for the same months last year.

All of the main causes of fatal accidents show reduced fatality rates per million tons in 1924, as indicated by the following figures:

	Jan.-Feb. 1923	Jan.-Feb. 1924
Falls of roof and coal.....	1.819	1.633
Haulage.....	.680	.473
Gas and dust explosions.....	1.314	.723
Explosives.....	.128	.125
Electricity.....	.110	.072

Moses Weakening on Printing
Of Coal Commission Report

While it has been impossible to convince Senator Moses, of New Hampshire, chairman of the Senate Committee on Printing, that the report of the Harding Coal Commission should be printed, he did show signs of weakening last week when his attention was called to an opinion that his action is one of the best cases on record of foregoing the harvest as an economy after the expense of producing the crop.

The printing of the entire report, a portion of which was not mimeographed, will cost, the Public Printer estimates, \$22,000. An effort now is being made to exclude certain portions of the report and a new estimate is being prepared.

Coal Consumption and Power
Output by Utilities Higher

Electric public-utility plants consumed 3,627,322 net tons of coal during January, according to a report just issued by the U. S. Geological Survey. This compares with 3,392,983 tons consumed in December and 3,474,152 tons in November. Fuel oil consumed by utility plants in January totaled 1,562,622 barrels, compared with 1,473,045 barrels in December and 1,379,281 barrels in November.

The average daily production of electricity by public-utility power plants during January was 167,000,000 kw.-hr., which exceeded all previous records, being 3.5 per cent higher than in November, last, when the previous high mark was set.

Coal-Mine Fatalities During February, 1924, by Causes and States

(Compiled by Bureau of Mines and Published by Coal Age)

State	Underground											Shaft				Surface				Total by States

B. M. Clark Sees Gloomy Outlook for Central Pennsylvania with Renewed Pact

The outlook for business in the coal mines of central Pennsylvania under the present agreement is not at all reassuring, according to a statement issued April 4 by B. M. Clark, president of the Central Pennsylvania Coal Producers' Association. "The renewal of the wage agreement for three years at Philadelphia," said Mr. Clark, was in line with the generally accepted policy throughout the United States, to take the coal business out of the public eye and to bring peace to the industry, which has been in a chaotic condition since the outbreak of the European War.

"That section of the industry which maintains its relations with its employees through the United Mine Workers, and is generally described as unionized, in renewing the agreement for three years took into consideration the effect upon the public mind of another great coal strike. It also is the opinion of many of the leading coal operators that the operation of economic forces would bring about any adjustments that may be necessary in wages or other conditions in the industry. It is also the opinion of these operators that the peaceful method of adjusting the coal industry to present business conditions can be brought about more satisfactorily without a strike than with one.

High Wage Scale a Mistake

"If business conditions in the industry remain as bad as they are today—and indications are they will grow worse—the miners and operators will soon be brought to realize the mistake of trying to maintain a very high wage scale in the face of the overwhelming force of competition from fields where wage rates are much lower and accordingly production costs much lower than they are in the unionized sections of the industry.

"At the present time in central Pennsylvania there are approximately 550 tippie mines completely idle out of a total number of 1,000. These mines represent about 50 per cent of the productive capacity of the district, or, roughly speaking, 2,500 carloads per day, and employ about 30,000 men. Of these 30,000 men a number have gone to work in other union mines in the district; some have gone to work in other occupations, and still others have gone to work in mines operating in the non-union section of Pennsylvania.

"It is conservatively estimated that of the 30,000 men formerly working in the mines that are now totally idle, about 12,000 have found work as indicated. This would leave 18,000 idle miners now in the district. The mines that are at work, generally speaking, are working from two to three days per week. Their production per day has been increased by higher efficiency of the men due to short running time and by the additional men obtained from the mines that are totally idle, so that the working time of the regular employees in mines still at work is being constantly decreased.

"Many of the mines that have been operating have been filling contracts that were made a year ago. Practically 85 per cent of the coal contracts expire at the end of the coal year, April 1. The present low prices offered for contract business have precluded the possibility of many central Pennsylvania producers taking business this coal year. Railroad-fuel contracts are being made at prices below the cost of production under the union scale in central Pennsylvania. This also is true of other contractors such as public utilities, manufacturing and industrial plants. The net result of this condition is that there is only about 30 per cent of the total volume of contract business on the books of central Pennsylvania operators today as compared with the amount of such business on the books of the same operators one year ago.

Working Time at Low Level

"The full significance of this statement may be grasped by the following tabulation of working time of the total 653 tippie mines located on the Pennsylvania R.R. in the central Pennsylvania district:

Mines idle	341
Mines working 1 day	49
Mines working 2 days	60
Mines working 3 days	56
Mines working 4 days	65
Mines working 5 days	51
Mines working 6 days	31
653	

"On the New York Central, out of a total of 190 mines, 86 are completely closed down. This also is true on the Pittsburgh & Shawmut and Pittsburgh, Shawmut & Northern railroads.

"The Buffalo, Rochester & Pittsburgh Ry. is one of the largest coal-originating railroads in our district. Due to the fact that the contracts which the Rochester & Pittsburgh Coal & Iron Co. held for business last year have expired and the company has been unable to renew them under the present conditions, the company has closed its mines located in Helvetia, Eleanor, Adrian, Aultman, Ernest, McIntyre, Snyder, Coy, Whiskey Run and Nesbit Run. These mines when working produce 11,000 tons per day and employ 3,000 men.

"Practically every mine in the Broad Top region, where they employ 1,200 miners, is now idle without hope of operation in the near future. Mines employing about 1,000 men on the Allegheny Valley division of the Pennsylvania R.R. in our district have been idle for months, and this condition will continue.

"The total production of the central Pennsylvania district should exceed 60,000,000 tons per year. The union mines in the central Pennsylvania district ought to produce 45,000,000 tons of this amount. It is agreed by many men in the business that the union mines in central Pennsylvania will not produce, if the present situation continues throughout the coal year, more than 15,000,000 tons, or a loss to the unionized mines of central Pennsylvania of a possible production of 30,000,000 tons.

Monongahela Field Adopts Jacksonville Agreement

At a joint wage conference of the Monongahela Coal Operators Association of West Virginia and representatives of the United Mine Workers, held in New York City on April 2 and 3, the Jacksonville agreement was adopted effective three years from March 31.

"The labor cost of producing coal in central Pennsylvania under the union scale is approximately \$2 per ton. The mines in the non-union fields of Pennsylvania that have reduced their wages to what is known as the 1917 base can produce coal at \$1.40 labor cost per ton. The present wages paid in the Pocahontas field of West Virginia will permit production of coal at a labor cost of \$0.90 per ton. Present wages in the New River field of West Virginia will permit production of coal at a labor cost of \$1.12 per ton. These figures, of course, do not include the cost of supplies and general overhead. Labor cost is only 70 per cent of the total cost of production. These fields have a productive capacity of about 50,000,000 tons of the same quality and character of coal—namely, low volatile—as is produced in the central Pennsylvania district and is sold in the same markets.

"The full force of this competition is now reflecting itself in the idle mines and miners in the union fields of central Pennsylvania."

No Wage Adjustment in New River Field

Adjustments of wages and working conditions have not been necessary this year in the New River field of West Virginia, as in other years, so that the new coal year was ushered in without much attention. With the disintegration of District No. 29, which formerly embraced the New River field, miners and operators in that field have been free to make their own agreements for the last two years and wage scales and working conditions have been worked out in that way, with wages rising as prices rose and with wages lowered as prices dropped to the point where the operators could no longer pay the higher wages so that under existing conditions New River mines are paying their employees on the basis of the 1917 wage scale. There are a few exceptions of course, among them the Low Moor company, the New River, Pocahontas Consolidated and the Fordson company.

Even with lower wages in effect however the market is in such shape that operations are becoming more irregular and many concerns are operating at a loss but are nevertheless continuing operations in order to afford employment to their men and in order to hold their organizations together.

In such sections as Keeney's Creek, where miners have been employed in connection with development work, it has been necessary to give the men furloughs.

Brophy Refutes Clark

Clearfield, Pa., April 7.—John Brophy, president of district No. 2, United Mine Workers of America, has issued the following statement in reply to B. M. Clark, president of the Association of Bituminous Coal Operators of Central Pennsylvania:

"Last week at Philadelphia the operators of central Pennsylvania signed a wage agreement for three years. This week they say, 'It can't be done.'"

"They said the agreement was made in order to take the coal business out of the public eye. But is it taken out of the public eye when they issue such statements in the press as that released on April 4, in which they predict that the whole district is going to the demnation bow-wows?"

"They tell us there are many idle mines in the district. We agree with them—we are very well aware of the fact. But their statement is misleading because it fails to state that the other bituminous fields throughout the country are in the same (or worse) plight."

"For a remedy they suggest the same old panacea they have been offering for the last thirty years—lower wages."

"They say competition is too keen to admit of high wages—if wages were lower they would get more orders and the miners would get more work. They tell of the non-union fields of West Virginia, where the wages are far below the union rates. But do the low wages there provide steady work? The last report of the Geological Survey (March 29), which covered the week ending March 15, shows the New River field producing 46.9 per cent of capacity; the Pocahontas field producing 54.9 per cent of capacity; the central Pennsylvania field producing 55.3 per cent of capacity, and the non-union Maryland field was producing only 38.7 per cent."

"The miners know full well that lower wages never increase the opportunity to work but only decrease their earnings and will not agree to any such 'wage adjustment' as suggested in the operators' statement."

James Brown

"Jamie" Brown, Scotch coal miner, is extremely busy these days "learning the ropes" to play the principal part as King George's representative during his residence at Holyrood Palace next month in the capacity of Lord High Commissioner to the General Assembly of the Church of Scotland. He is being advised and assisted in the intricacies of the forthcoming ceremonies by the Duke of Atholl, former High Commissioner. The Duchess of Atholl has put her knowledge at the disposal of Mrs. Brown, a former mill girl, and the Marchioness of Ayr, wife of the Lord Lieutenant of the County of Ayr, will be lady in waiting to "Mrs. Jamie."

"The truth of the matter is that the bituminous-coal industry is overdeveloped and will stay in the public eye until some order is brought into it. We now have a capacity sufficient to produce twice as much coal as the market can consume. Consequently slack work is a chronic disease of the industry and will remain so until something is done to check development in order to permit demand to catch up with production."

Coal Co. Allowed \$373,401 Amortization Claim

J. M. Clack, an auditor of the Internal Revenue Bureau, which is being investigated by the Finance subcommittee of the Senate, explained to the subcommittee the tax case of the Berwind-White Coal Mining Co. of Philadelphia, which had been mentioned before the committee as one concern that had its case reopened after an amortization claim had been disallowed. It put in a claim for amortization for 1918 of \$257,668.16, and for 1919 of \$66,966.10, a total of \$324,634.26, on a power plant that was built to assist in the operation of coal mines during the war.

A revised claim was filed Oct. 1, 1921, for \$575,591.31 amortization. The increase was explained as being due to the fact that the 1918 law put a limitation of 25 per cent on deductions for amortization. Engineers C. G. Woolson and J. P. Moore examined the return and on May 12, 1922, recommended that the claim be disallowed in full. Their reason was given as being that the plant had no excess operating capacity on account of the war, but was needed for post-war activities.

A new investigation was made on protest of the company and Engineer J. W. Swaren recommended an amortization allowance of \$176,953.25. The taxpayer protested this. A re-examination was made and on Nov. 18, 1922, an allowance was made of \$373,401. This was based, it was stated, on additional data and was the result of conferences.

Mr. Clack added that the uniform practice had been to allow amortization to coal companies on their plants erected during the war to take care of increased production.

Senator Couzens said the successive steps in the case of the Berwind-White company disclosed the chance for questionable conduct in the handling of these income tax cases.

"There is an enormous responsibility of the department," the Senator continued, "and this shows the opportunity for favoritism, influence, and even for graft, which I do not charge."

Problems In Underground Management

How Far Beyond Excavated Area Is Surface Broken?

Many British inquiries into the character of subsidence have shown that the surface of the ground is broken considerably back of the line of fracture in the excavation below. The angle between a vertical line from the face of the excavation and a line drawn from the point of break on the surface down to the face is called the angle of draw because owing to the tensional stresses

Neutral Surface Near the Coal

Where the material is stronger to resist compression than tension the surface of no strain or neutral surface lies near the coal.

the measures are broken beyond the coal face.

Ira C. F. Statham in a thoughtful paper read before the Yorkshire branch of the Institute of Mine Surveyors of Great Britain summarizes the findings in various parts of that country. Of course, the roof does not subside at the point where the draw or fracture from tension takes place. It is the point of break at the surface and not the point of subsidence. In fact though Mr. Statham does not say so, the surface actually may rise at that point. The coal being crushed, however, the area of actual subsidence is larger than the area of excavation, for the face of the coal is crushed downward under the

load and the clay is squeezed out into the excavated area.

Among Mr. Statham's notable remarks is the following: "Rocks are stronger in compression than in tension. The average figures for sandstone are: Tensile strength in short tons per square inch 0.46; compressive strength 3.93; hence sandstone is about nine times as strong in compression as in tension, so that the neutral axis will be roughly one-ninth of the depth above the seam or eight-ninths below the surface." Apparently he believes the roof below the neutral axis breaks in a line over the excavation and that this break at the neutral axis meets another break extending down from the point of draw on the surface, this fracture, of course, making a larger angle with the vertical than the line of draw. Most of us

As Statham Views Roof Fracture

The roof does not fracture from *a* to *c* but breaks forward to *b* which is on the neutral surface and backward to *c* at the surface. This is an interesting viewpoint. Some have thought the nether roof which did not constitute part of the monolithic roof broke over the excavation, but Mr. Statham declares it is that part of the roof proper below the neutral surface which breaks in that manner.

How Subsidence Develops

Mr. Statham designates three zones, the dead or subsided area, the motive or subsiding area and the littoral zone which lies over the standing coal and moves but little.

would be disposed to believe that the break over the excavation was an entirely unrelated break in the nether roof or draw slate which does not form any part of what Mr. Statham well names the "absolute" roof. But as no one has ever been immured in the roof when it tore apart, possibly this question may not be settled for some time. Here are two breaks of unlike direction, what more simple explanation can be imagined than that they meet at an angle on the neutral axis or neutral surface? So that is where Mr. Statham places it, probably without any justification.

Observations show, says Mr. Statham, that not only breaks but also actual subsidence commences ahead of the coal face or over the solid coal and is a maximum behind the coal face.

Practical Pointers For Electrical And Mechanical Men

Cheap and Efficient Battery Transfer Rack

By constructing the battery compartments of storage-battery locomotives so that one man can readily remove and replace them the cost of operation is often considerably reduced. Sometimes it is convenient to be able to use a chassis for more than one shift thus saving the purchase of an additional locomotive. In that case the unit should be provided with two batteries and with means for their rapid interchange. A removable battery arrangement is also desirable where charging must be done during the day, no power being available for night charging.

Where the battery on the chassis is not sufficient to do a day's work the locomotive may often be enabled to give satisfactory service when an additional battery is provided and arrangements are made for the quick replacement of one battery by another.

There are, of course, many ways of removing battery compartments and conditions at the mine will determine the best method to be adopted. However, what undoubtedly is the cheapest and easiest method of accomplishing this operation is shown in the accompanying drawing. This method is recommended by the Ironton Engine Co. It avoids the introduction of additional tracks with their frogs and switches, thus saving much space. It does away with the older method of lifting the battery.

Rollers are provided on the chassis and similar rollers on platforms at either side of the track. Racks are provided on the bottom of the battery compartment and arranged to engage spur pinions mounted on the chassis, and driven by a roller chain, and sprockets through spur gearing to which a removable crank is attached.

With this system, and without any

especial effort, a change of batteries has been made in five minutes. This includes disconnecting the discharged battery, removing it, putting on a charged battery and connecting it up, ready for use. This would not be possible with any arrangement that required the shifting of the locomotive from one track to another.

One man working the crank can easily move off the discharged battery and move on the charged one. With this arrangement as only one track is required the locomotive chassis does not have to be pushed around by hand from one track to another when the transfer of the battery is being made. Space must be provided on each side of the track sufficient to store one battery, but a series of these platforms can be provided on the same track to take care of any number of locomotives.

Bell-Ringing Battery Floats On Automatic Charger

A number of mining companies in the anthracite field are now installing Magnar vibrating rectifiers and nine-cell storage batteries on shaft and slope signal systems. The rectifier and battery are usually placed in the engine house outside, the former being connected to the 110-volt alternating-current circuit. The rectifier is equipped with a small vibrating unit which charges the battery continually at from 0.1 to 0.5 amp. The signal bell circuit is in series with the battery.

When the outfit is installed the resistor on the charger is set at 3/10 amp. and by checking the gravity of the battery for the first two or three days, it is possible to regulate the current to the proper charging value. The plan is to float the battery on the charging circuit so as to charge at a rate fractionally higher than the load

Battery Floats on Charger

This little rectifier keeps the battery fully charged, thus greatly increasing its life. Renewals are infrequent and proper voltage is always available for the whole signal system.

which the signal bell circuit puts upon the battery.

The rectifier has proved to be dependable. There is little wear and tear on the vibrating contacts, and in case of a power interruption the vibrator stops and starts again with the resumption of power. The battery should be made up of nine 2-volt cells of from 35 to 40 ampere-hour capacity. In this class of service the battery lasts from 5 to 6 years.

The battery is always in a practically fully charged condition—most of the acid is out of the plates and in the solution, thus considerably increasing the life.

Don't Blame Mine for the Faults of Those in It

A recent article by T. F. McCarthy, published in *Coal Age* on the subject of the care of electrical mine equipment, prompts me to make the following comments:

We all know that the conditions under which electrical equipment must operate in the mines are necessarily bad, for moisture and dust are always present. However, we too often hear some one say that a certain piece of equipment is not operating satisfactorily because the mine conditions are unfavorable. Breakdowns and delays are not always ascribable to this cause. Often, I have almost come to believe that a fuse on a direct-current coal cutter is an accessory which has been practically forgotten. I have seen only too many fuse blocks which have been tampered with and damaged, because some one has replaced the proper fuse with a rail spike, or a heavy piece of copper wire.

Much of the high maintenance cost on locomotives is due to broken track bonds, which are allowed to continue as such until the locomotive absolutely refuses to move its load. Another cause

One Man Can Transfer Battery in Five Minutes

The locomotive stops between the two platforms and delivers its battery to the empty platform, taking a fully charged battery from the opposite side of the track.

It will be noticed that both platforms are equipped with charging cable thus obviating the necessity of any additional handling of the discharged battery.

of high maintenance to haulage equipment is the bad condition of the feeder circuits. Very seldom do we find the feeder wire properly spliced or tapped, so as to form a low-resistant joint. Cables are often suspended on props by means of spikes and in many cases both the positive and negative wires may be found buried in rocks and mud.

A serious offense often committed by locomotive motormen is to apply the hand brake so as to block the locomotive wheels before the controller is turned on. I have seen motormen do this and then turn the controller to the "full-on" position, after which they would gradually release the brake and slowly start the loaded trip. Then again, many battery locomotives are required to operate under full load for from eight to sixteen hours, and the battery is charged in from four to eight hours. Naturally, a very high current is needed to charge the battery in so short a time and its capacity and life are seriously affected.

On one occasion, I found a gathering pump motor driving its load through a gear which was submerged in about 4 in. of water. The motor was of the open type and the water picked up by the gear was carried directly onto the commutator and windings. These and similar conditions exist in nearly every mine with which I have been acquainted, and it is my opinion that much can be done to reduce the maintenance cost of mine electrical equipment by giving the apparatus reasonable attention, and by placing it where conditions of operation are favorable and are so maintained.

Linton, Ind.

J. R. LUXTON.

Protecting Motor-Generators And Rotary Converters

In an article on direct-current circuit breakers by Royce L. Grimes, which appeared in the Feb. 7 issue of *Coal Age* are remarks on the protection of rotary converters and motor-generator sets.

In one part of this article Mr. Grimes pointed out the danger of the load on one of several interconnected machines increasing to a point where the direct-current circuit breaker should open up but fails to do so, either due to the type of the breaker used or to some part not functioning properly. It is true that if such machines were connected in parallel with other direct-current generators and the load was sufficiently high to trip the alternating-current circuit breaker, serious trouble would almost certainly result.

To meet just such conditions it has been the practice of our company to supply standard control equipment for synchronous converters, induction motor-generator sets, and synchronous motor-generator sets, with alternating-current and direct-current breakers so interlocked that in case the alternating-current breaker is opened for any cause whatever, the direct-current breaker will also be tripped open. Incidentally, it may be added that this protective feature is furnished not only when the machines operate in parallel with another source of power but also when used independently. We have always found this necessary because in the de-

velopment of the electrical system of a mine it is quite probable that some machines originally operated separately will be tied in together. When this occurs it will be essential that this protective feature be installed and in operation.

Whenever any type of converter unit is operated in parallel with a direct-current generator, driven by a direct-connected prime mover such as a water-wheel or steam turbine, we furnish, in addition to the interlocking circuit mentioned above, a reverse-current relay. This relay is connected so that it will trip both the alternating-current and direct-current breakers at a current value sufficiently low to insure that the machine will be stopped before it has reached such a speed as will cause the overspeed trip to function. This is added protection to prevent the possibility of any mechanical damage to the commutator and the windings of the machine which might otherwise result if the machine should overspeed.

When power-converting machines are operated with their direct-current ends in parallel, but with their alternating-current ends fed from different alternating-current circuits a reverse-current relay is furnished and connected so that both the alternating and direct-current systems will be disconnected from the machines in case of failure of alternating-current power supply. Such protection as this is no doubt better than any other yet designed, because it does not depend upon the speed of the machine, thus making the possibility of any danger more remote.

Cleating and Supporting Copper

Properly supported copper stands up well against vibration. In fact, one finds it extensively used in certain applications where vibration occurs, because of its good behavior in this respect. But improperly supported, copper fails miserably under vibration. This point is frequently ignored in connecting car wiring cables to the motor leads when cleats are not applied. Care should be observed to study this point with the purpose of properly locating the cleats in supporting the cables. It often happens that the weight of a solid connector, even though it may look rather small, is sufficient under vibration to cause the copper strap or stranded cable to break at a point just behind the connector where stresses are localized.

Sickness of Copper

Copper is subject to a form of sickness which so far as has been experienced is peculiar to copper alone. All commercial copper contains a small amount of oxygen in the form of copper oxide, without which it has poor mechanical characteristics. When it is heated in a flame which is rich in free hydrogen, this hydrogen unites with oxygen, forming free copper and steam.

It is a peculiar characteristic that the hydrogen will readily enter the hot copper, but the steam cannot get out. The copper is thus not only weakened by the elimination of the copper oxide but the high pressure steam expands, producing a spongy effect which still further weakens the copper. This effect is, of course, greatest near the surface. This peculiar form of sickness should be guarded against by the operating men.

Safety Fuse Box Proves Successful

The accompanying illustration shows a fuse box which we are using on outdoor circuits. Its peculiar advantages around mining properties lies in the fact that when it becomes necessary to renew the fuse the door of the box acts as a switch and the fuse is replaced between two "dead" clips.

The box may easily be placed on a cross-arm in a position where it will be impossible for the workman to come in contact with an electrically charged conductor. Whenever a section of a line must be cut off for test or repair the fuse box may be opened and used as an extra protection against accident.

O. E. KENWORTHY.

Combination Fuse and Switch Compartment

This fuse may be replaced with absolute safety even if some one may have forgotten to cut off the power. When the door of the fuse compartment is opened the circuit is broken and the fuse is replaced in the two "dead" clips on the door.

Production And the Market

Coal Markets Continue to Display No Animation; Contracting Backward; Strike Menace Recedes

April 1 has come and gone and the soft-coal market is rapidly getting no better. For weeks the consumer has been awaiting the coming of that fateful day—"to see what would happen" before making a move in the coal market. Not much happened, and he hasn't done a great deal about it. Industrial clouds continue to disappear from the horizon as one by one district settlements are signed, northern West Virginia and central Pennsylvania, which came in last week, having been followed by the Monongahela district, which also signed up for three years. Agreements in Kanawha and western Kentucky have been deferred and the Southwestern fields and Alberta have completely suspended.

While these successive adjustments of wages and working conditions are hailed in many quarters as an assurance of industrial peace, the consumer interprets them as removing the incentive to buy coal and seems to have decided to play the waiting game to the limit. Even the contract business usually in evidence at this time is far behind the seasonal level.

Coal Age Index declined 2 points to 171, as of April 7, the corresponding price being \$2.07. This compares with \$2.09 on March 31.

Steam Prices Firmer in Middle West

Steam coals in Illinois and Indiana are somewhat firmer, most of the other sizes being in difficulty. "No bills" are much in evidence. Business is hard to get in Franklin County, the mines that are running getting from two to three days a week. Duquoin and Jackson County find it even worse, many mines closing down and the others working only one and two days a week. Demand for screenings is good in the Standard field, but little else that is favorable can be reported.

Kentucky markets are unsettled pending a wage settlement, April 15, and little business is being booked.

Business in the Northwest has gone flat, prices having broken as the result of some dock companies making cuts and the others following suit, but business is not eagerly sought at the reduced level. The spurt of brisk business in the Southwest continued right up to April 1, when operations were suspended until a wage agreement shall have been negotiated. A cold snap in Colorado and Utah has helped business there, and the outlook is still bright.

Better Tone in Cincinnati Market

Buying in Ohio markets is at a low ebb, the trade in general being quiet, though the tone at Cincinnati is better. Contracting for steam tonnage is lagging, awaiting prices on railroad fuel, and production is falling off steadily. Not a ray of hope is discernible through the deadly dullness that has settled over New England—low as production has fallen, demand is too meager to absorb it. Consumers are indifferent in the Atlantic seaboard markets. Supply and demand in West Virginia are more nearly equal, and as a result prices are more stable.

Production of bituminous coal during the week ended March 29, according to the Geological Survey, amounted to 8,837,000 net tons, which was 424,000 tons less than was produced during the previous week. Output of anthracite totaled 1,942,000 net tons, an increase of 138,000 tons compared with the preceding week.

New price circulars on anthracite came out April 1, reductions by the companies on domestic sizes ranging from 40c. to 60c., except on pea, on which the cut ranged up to \$1.15. Reductions on steam sizes range from 35c. to 50c. on buckwheat and from 25c. to 50c. on rice, there being no cut in the price of barley. Independents are said to be shading prices in order to move their product.

Midwest Steam Firms Up

A slight firming up of steam coal in Illinois and Indiana was the only change marked during the week in the Midwest market. This was insufficient to change prices much, but most steam coals stuck closer to circular than they have been doing. Most other sizes were in trouble in those states, however. "No bills" in all the domestic sizes were backing up in southern Illinois in spite of an earnest effort to move them and of the recent cut in their prices. Some business is expected in this district from the Missouri Valley region since the shutdown of the Southwestern Interstate district mines of Kansas, Oklahoma and Missouri, but the effect of the shutdown has not yet had time to make any great difference.

The domestic trade of the Midwest region is taking a little Pocahontas at the prevailing \$2@2.25 price on mine run and \$3@3.25 on lump and egg, but the volume is small. The April 1 cut in anthracite started a small movement of hard coal in domestic sizes to dealers throughout the Midwest region, as was expected. A good many dealers had withheld orders for two or three weeks before April 1 awaiting the drop. Present prices are expected to prevail throughout the summer.

Such mines as are open are getting from two to three days per week in Franklin County and all mines have "no bills" in some sizes. Railroad tonnage has practically stopped. The independent operators are having a hard time getting any business, in view of low prices made by the organization operators. In the Duquoin and Jackson County fields most mines are shutting down and business is hard to find with mines working one and two days a week.

In the Mt. Olive district business is bad. Steam sizes are in good demand, but lump fails to move. The operators at Mt. Olive are asking \$2.75@2.85 on 2-in. and 3-in. lump, whereas 6-in. lump from surrounding mines is selling as low as \$2.65. In the Standard district screenings are in good demand. Everything else is just plugging along with many mines shutting down and all mines with "no bills."

Cool weather keeps St. Louis coal yards busy, on small lots principally and on the cheaper grades. The only change in the market has been that of Carterville, which was reduced from \$8 to \$7.25 and \$7.50. There is a fairly good demand for this in small quantities. Anthracite, smokeless and coke are a little bit slow, with new prices expected at once. The new prices on coke are: Byproduct, \$10.75; gas-house, \$10.25, for sidewalk delivery. Local steam wagonload is good and carload is fairly active. Country domestic is

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924	1923
April 7	171	233
March 31	173	233
March 24	176	233
April 9	207	233
Weighted average price	\$2.07	\$2.13

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

fairly good for cheaper grades; country steam is quiet.

Business is better at this particular season this year than in many years, considering the fact that there is no strike, and on the other hand nothing that would indicate a prosperous territory in the vicinity of St. Louis.

Kentucky Is Upset

Failure of the operators and union leaders to reach a wage scale agreement and extension of the old contract to April 15 leaves the western Kentucky field in an unsettled condition, as operators do not know what conditions will prevail after April 15, and are unable to book much business. Some sections are taking the bull by the horns and going non-union now, their old contracts having expired, regardless of the extension at Louisville.

Demand for coal is very quiet, and while western Kentucky screenings have advanced from 90c. to \$1.10@1.35 it is due principally to lack of production rather than real demand. Mines are operating from one day to a day and a half a week, with just a few getting in two days. Prices of prepared sizes have slumped off, and egg, lump and block are all quoted at \$2.25@2.50 this week, and probably can be shaded a little in some instances.

Some eastern Kentucky operators are asking \$2.75 and even \$3 for block coal, but \$2.50 appears to be about the top at this time. Many of the eastern Kentucky mines are non-union, and can therefore make the price without hurting themselves; the rest are being forced to come to it. Some contract business is pending, but no new business has been reported as placed over the past several days, although railroad contracts are due. There is no early inquiry on Lake business.

Northwest Trade Goes Flat

The market has dropped off at Duluth all around, with bituminous suffering to the extent of \$1 to \$1.50 and anthracite off about 25c. The break was caused by three dock companies which sent around a circular letter cutting prices, and the other companies followed suit. The prices are: Kentucky lump, \$5.50; mine run, \$5; screenings, \$4.25; Youghiogheny lump, \$5; mine run, \$4.50; screenings, \$4; Hocking lump, \$5; mine run, \$4.50; screenings, \$3.75; Splint lump, \$5; mine run, \$4.50; screenings, \$4.25; Pocahontas lump, \$7; mine run, \$5.75; screenings, \$4.75. Anthracite prices are these: Stove, \$13; egg, \$12.70; nut, \$13; pea, \$10; buckwheat, \$8. The market has no activity. The docks are not anxious to sell at the new prices, as they claim they will lose money, and the public is showing no disposition to buy.

The coal market continues quiet at Milwaukee with demand for domestic grades fluctuating with weather conditions. The steam trade also is light. Consumers who put in heavy supplies last autumn in anticipation of a strike in the spring are now working off their surplus.

April brought a reduction of 50c. per ton on anthracite and \$2 per ton on coke. Egg size hard coal is now held at retail at \$15.90; stove, \$16.30; nut, \$16.15; pea, \$13.80, and buckwheat, \$11, with an extra charge of 75c. per ton when coal is carried to bins. Large sizes of Solvay coke now sell at \$12.90 and pea coke at \$9.90. Gas coke is quoted at \$11.75 for egg and nut, and \$10 for small and pea coke. Dock companies announce that there will be no change in soft coal prices until May 1.

West Does Some Business

A brisk business preceded the closing of mines through the Southwestern district April 1, pending the agreement of operators and miners on a new wage scale. Industries and railroads bought heavily, leaving small surplus of screenings at the mines. Domestic sizes moved more slowly, and mines report some surplus. But, as it is generally expected that the suspension of work will continue through April, this is causing no worry.

Business continues fairly good in the Colorado coal market. Mines worked on an average of a little better than three and one-half days last week. The cheaper grades are the popular selling coals. The cold weather which has prevailed for the past few weeks is still hanging on and the outlook for next week appears bright. Prices are unchanged since March 1.

A cold snap in Salt Lake City has stimulated consumer demand, but industrial buying is light. The slack situation is improving a little as a result of the better demand for prepared sizes. Slack prices are 25 cents higher than last week, mine prices being \$2 for screen slack and \$1.50 for straight slack. Other mine prices are: Lump, \$4; domestic lump, \$3.50; stove, \$3; nut, \$2.50; pea, \$1.75. Retail prices are \$8, \$7.50, \$7, \$6.50, \$6 and \$5, respectively.

Improved Tone in Cincinnati

A better tone is observable in the Cincinnati market. Less "consignment" coal is coming to the market and "distress" coal that had been cluttering things up for three weeks, is moving. Pocahontas producers have cut production to actual contractual demands plus a reasonable allowance for current sales, which is about one or two days a week. Low-volatile business has perked up noticeably, New River and off-grade shippers bringing their prices more on a line with the circular of "standard" companies. The high-volatile trade also shows improved tone, the "don't care" attitude being less in evidence. The volume of business is still far below normal. Specialized coals are quoted as follows: Block, \$3@3.50; egg, \$2.25@2.75. Retailers were greeted with a flock of small orders on the heels of a cold snap, but prices remain unchanged.

Trade at Columbus continues quiet and featureless. Buying is at a low ebb both for steam and domestic tonnage, although some attention is being given to railroad-fuel contracts. General contracting for steam tonnage is being held up to ascertain prices on railroad fuel and it is believed that some contracting will take place the latter part of the present month. Prices are still low and irregular although there is not nearly as much distress coal on the market and quotations are working toward stability. Demand for steam tonnage is not large, as many of the larger consumers still have considerable surplus. Domestic trade is quiet as it is between seasons and dealers are cleaning

up. Production in Ohio is lower than at any time in months. Little has been done in contracting for late shipments.

About 20 to 30 per cent of the mines in eastern Ohio already have closed or are closing, due to lack of orders and there is no indication that this heaviness will lift in the near future, as large consumers are well stocked. Especially is this true of the railroads, public utilities and large steel plants. Because of the abundance of fuel, negotiation of contracts is being deferred, and it is likely that the major portion of tonnage moving during the new coal year will be in the open market rather than upon a contract basis. Due to the lower production of prepared sizes, slack and nut and slack have become less abundant and prices have stiffened 10 to 15c. per ton as compared with a week ago.

The situation at Buffalo has not changed materially. The market is markedly dull and the outlook is for a continuance of this state of things.

Production in the Pittsburgh district continues to decline. The decrease in shipments of gas lump decreased the supply of gas slack offered in the spot market, which is now up 5c. from a week ago. Steam slack also is higher, owing to the practical disappearance of domestic coal shipments. The spot market continues dull.

New England Market Drags

In New England the steam coal market drags along in discouraging fashion. New low levels at Hampton Roads are the only new feature. There are no developments for all-rail. The industries complain of dull business; neither in shoes nor in textiles nor in machinery is there demand sufficient to absorb current production. The prospect is so uniformly drab that practically no buyers are in the market.

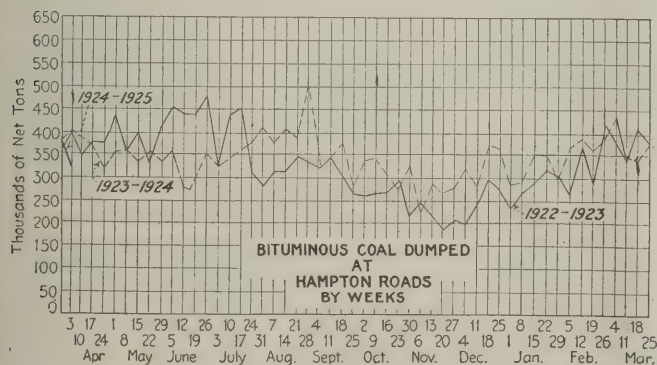

At Hampton Roads there are still heavy accumulations. The Western market is not particularly helpful and since operators seem disinclined to curtail there are likely to be further bargain sales at the Virginia terminals. A few sales of No. 1 Navy Standard Pocahontas and New River at \$4 flat have been rumored, but it is the impression of the trade that it would be difficult to pick up a cargo of any considerable size of really first-grade coal at less than \$4.15 per gross ton f.o.b. vessel.

On cars at Boston the quotations of the various factors are similarly depressed; \$5.50 per gross ton on cars has been an open price now for more than ten days, and there is a feeling among possible buyers that this figure will be materially shaded by certain of the agencies who have coal now en route for disposition inland from railroad wharves.

From central Pennsylvania all-rail there is likely to be decreasing movement, now that 1923 contracts have expired in so many instances. Neither via New York nor Philadelphia is coal being dumped in any volume worth mentioning. The differential in cost at seaboard operates so strongly in favor of Hampton Roads coals that April is certain to be a very light month for bituminous in Pennsylvania.

Seaboard Markets at Low Ebb

The coal trade at New York has settled down to a dull summer in the opinion of many coal men. Consumers are not showing any disposition to increase present stocks and operators are inclined to close more mines rather than operate at a loss. Complaint is current that considerable coal is now sold below the cost of production. Contract making is far below normal and demand in the spot market is at low ebb. Tidewater business is slow and there is some distress

coal in the New York harbor, but the tonnage is not large. Local houses are carefully watching the British situation, hopeful of obtaining some business if the miners go on strike. Quotations at Hampton Roads are off, but there is practically no foreign business being booked.

The ripple created at Philadelphia by the wage parley of the central Pennsylvania operators quickly melted away after the operators gave into the miners and adopted the union scale. Some shippers seemed to feel that the occasion warranted price increases, but it is doubtful if any considerable coal was sold at increased figures. Stockpiles continue to shrink and there is no indication that consumers will replace stock in the immediate future. Railroad buying also is quiet.

At Baltimore it is a "beggar's market," a case of survival of the fittest. The export outlook, however, is bright.

Prices are much better stabilized in West Virginia largely as a result of more limited production following a period during which coal was being literally thrown on the market. Even with production curtailed, demand is hardly equal to supply, but supply and demand are becoming more nearly equalized.

Market conditions at Birmingham show little change. Inquiry for spot steam coal is light and negotiation of contracts for industrial and railroad fuel has not assumed much proportions as yet. Reports indicate that producers of the better grades of domestic coal are comfortably sold up, in many instances for the entire year.

Anthracite Trade Dull Despite Price Cut

Reductions in the prices of domestic sizes of anthracite by the operating companies ranging from 40c. to 60c. on broken, egg, stove and chestnut coals and from 50c. to \$1.15 on pea coal failed to arouse any interest in New York so far as demand goes. There was no increase in movement, although retail dealers reported a fair volume of orders. Consumers show no anxiety about delivery although the present prices are for April only. Stocks in the retail yards are so large that consumers who ask for prompt delivery are easily accommodated. Independent operators, endeavoring to move their coals, often find it necessary to shade prices considerably in order to make shipments. Steam coals are moving in fair volume. Company reductions range from 35c. to 50c. on buckwheat and from 25c. to 50c. on rice. There was no cut in the price of barley, this remaining at \$1.50. A couple of the companies will make quotations only on application. A heavy snowfall on April 1 brought a busy week to Philadelphia dealers in delivering emergency orders, and on top of this they have received considerable business for cellar filling, yet the operators have fewer orders on their books now than in any spring for years. Though steam prices have been reduced, all shippers are finding difficulty to induce their contract trade to sign up. Retail prices at Baltimore have taken a tumble of between \$1 and \$1.25 per ton, the greatest drop in recent years in the history of the trade.

Foreign Market And Export News

Strong Domestic and Foreign Demand in British Market; Output Higher

Pressure is strong for immediate supplies on the Welsh coal market, and all the collieries are heavily booked right up to the date when the strike is due. Buyers have been influenced by the rejection by the miners of the operators' offer, which is regarded as generous. Demand is strong from both domestic and foreign buyers.

As a result of this pressure prices are rising strongly and many collieries are refusing new business until they have cleared off arrears occasioned by the rail and dock strikes. The impression is growing in some quarters, however, that the threatened strike will be averted, for some of the miners' associations are advising acceptance of the mine owners' proposals.

Loading congestion at South Wales is unabated, twenty-eight steamers awaiting berths although there is coal at the docks. The operators are trying to get the night loading shift at the docks reinstated to meet the rush for supplies, but with little success so far, the trimmers holding out for a 33½ per cent boost for the night shift.

The Newcastle market is firm for shipment up to April 15. Home demand is very strong but foreign buying has fallen off owing to the unsettled labor position, European exchanges and the dock strikes in Germany. British public-utility corporations are laying in heavy stocks against a miners' strike.

It is reported that Tyne has received a contract from the Paris, Lyons and Mediterranean Ry. for 400,000 tons of Durham coking coal, April-December loading. The French State Rys. also are seeking 60,000 tons for April-June delivery. A strike of Scottish coal trimmers is delaying Forth loadings. Rail deliveries to London are still badly congested.

Production by British collieries during the week ended March 22, a cable dispatch to *Coal Age* states, was 5,786,000 tons, according to the official reports. This compares with 5,778,000 tons in the week ended March 15.

Trade at Hampton Roads Dull But Hopeful

Dullness continues to mark the trade at Hampton Roads, with prices declining rapidly under distress orders, to save demurrage on large accumulations at tide. Export business has dropped slightly, while coastwise trade is barely holding its own. Bunkers show a slight gain.

Contracts are scarce, despite expectations that April 1 would bring large bookings. The tone of the market is rather weak, although the trade is optimistic, with a fair outlook.

Activities at the piers during March reflected a generally growing coal movement, under unfavorable conditions. The decline of the market was responsible for dullness here.

Industrial Demand Absorbs French Coal Output

Demand from industrial consumers in the French markets is ample to absorb the output. Trade in coal for household use, however, has eased up. The French collieries are receiving a large number of orders for replacement of purchases usually made abroad. Nevertheless, imports of British coals have been larger during recent weeks following the strikes in England.

Transportation has become easier during the week, due to an improvement in the supply of rolling stock.

Reparation deliveries to France and Luxemburg during the month of February were 332,700 tons of coal, 410,600 tons of coke and 65,000 tons of lignite briquets, a total of 808,700 tons, as compared with 775,900 tons in January and 584,000 tons in December. Deliveries to Belgium in February were 408,727 tons, including 53,587 tons of coke and 9,635 tons of lignite briquets.

The production of the Ruhr coal basin in February was 7,050,758 tons of coal (against 6,187,452 tons in Janu-

ary), including 6,371,451 tons for the occupied regions (as compared to 5,485,040 tons in January); 1,298,556 tons of coke (against 1,097,722 tons in January), a total for the occupied areas of 1,147,592 tons (against 881,910 tons in January). The results of the direct working of the mines and cokeries under Franco-Belgian administration are not included in the above figures.

News Items From Field and Trade

ALABAMA

George C. Randall, formerly manager of the southwest division of the American Railway Association, Dallas, Texas, has been appointed district manager of the association for the Southeastern division, according to announcement of M. J. Gormley, chairman. Mr. Randall succeeds S. H. Charles, who died recently.

ILLINOIS

The Central Illinois Coal Traffic Bureau has dissolved. It ceased to function April 1, when its office lease ran out in the Old Colony Building, Chicago. W. A. Holley, manager of the bureau for several years, is counting on enjoying a summer of ease for once in his life. G. B. Hemphill, who was assistant to the manager, has joined the Chicago Coal Merchants Association as traffic manager with offices in the Transportation Building.

The West mine broke its record again March 27, when 6,045.85 tons was hoisted in eight hours. The previous record was 6,020.25 tons made on Nov. 27, 1923. To make the record there were 1,239 hoists. No. 9 mine is known as West mine in Nokomis. Average tonnage for month of March was 5,742 tons per day. F. W. Schneider is mine manager at No. 9 mine, and E. H. Hebenstreit is superintendent of the company.

The Franklin County Coal Co., formerly the Taylor Coal Co., has sold its retail department in Chicago to Wright & Co., of Chicago. The Taylor retail division controlled a small dock and did a considerable business in steam coal for Chicago downtown buildings. Its manager, R. H. Hatfield, joins Wright & Co.

INDIANA

The Sugar Valley Mining Corporation, Terre Haute capitalized at \$50,000, has filed articles of incorporation with the Vigo County Recorder. This company will lease from the Macksville Mining Company, recently incorporated for \$500,000, the Sugar Valley mine, operated by the Sugar Valley Coal Co. before it went into the hands of a receiver. Directors of the new corporation are John F. O'Brien, Joseph Mullikin, A. J. Beasley, Edwin H. Long and Arthur C. Boston. Directors say the Macksville Co. and the newly incorporated company are the same, with the exception that the new organization has a few additional stockholders. Eventually, it is said, the Macksville Co. will dissolve.

Seventeen months of litigation in the federal court over the Central Indiana R.R., known as the "Indiana Coal Road," ended recently when Judge A. B. Anderson entered a decree discharging William Pirtle Herod as receiver. The Central Indiana Railway Co. will operate the road. A fee of \$25,000 was allowed Herod for his services. The road is between Muncie and Brazil, and goes through the coal fields. The latest difficulties of the old Midland began when the Central Union Trust Co., of New York, filed a complaint against it. It was ordered sold by Judge Anderson, but Charles Martindale, master in chancery, could find no buyer. The decree of sale was returned unexecuted. The new decree set out that all outstanding obligations had been cared for and mortgages had been satisfied. Herod was ordered to give up all property that he held as receiver to the Central Railway Co. The company assumed liability for all claims.

KANSAS

Kansas coal mines produced 4,650,479 tons in 1923, an increase of 1,132,236 tons over the output of the preceding year, according to the annual report of James Sherwood, who retired as state mine inspector on April 1 and was succeeded by Leon Besson. Crawford County deep mines produced 3,091,743 tons, or 87 per cent of the total; Crawford County strip mines 324,545 tons, or 7 per cent; Cherokee County deep mines 392,392 tons, or 8

per cent; Cherokee County strip mines 337,327 tons, or 7 per cent. The chief producers outside these principal fields of the state were Leavenworth County, with 137,563 tons, and Osage County, with 74,047 tons. The total number of men employed in mining was 10,459, an increase of 383 over the preceding year. The mines averaged 118 days' work, a decrease from 1922.

KENTUCKY

The Columbus Mining Co., 332 Michigan Ave., Chicago, Ill., is contemplating doubling the size of its No. 5 mine at Al-lais, by opening two seams on the side of a hill across a valley from its present tippie. A long conveyor is to run up the slope, connecting the new operations with the old tippie. Allen & Garcia, of Chicago, are the engineers.

Federal Judge A. M. J. Cochran, Eastern Kentucky division, in a decision at Frankfort, on April 2, granted a temporary injunction to the Liberty Coal & Coke Co., on Straight Creek, in Bell County, restraining members of District No. 19, United Mine Workers, from interfering with operation of the company's mines and with its employees. The judge has under advisement contempt proceedings against union miners charged with violation of a previous injunction.

A report from Harlan, Ky., under date of March 31, stated that the Henry Ford interests, operators of the Banner Fork mines on Wallins Creek, were planning a million dollar water-power development to furnish power to Ford operations.

It is reported from Whitesburg that W. J. Wray and Thomas Miller, of Northfork, W. Va., connected with the Elkhorn-Hazard Coal Co., operating at Sandlick, were recently in Whitesburg, making arrangements for enlargement of the company operations, the concern planning expenditure of around \$100,000 in improvements. It was also reported that the Reliance Coal Co., Cincinnati, is erecting sixty additional miners' homes at the Glomawr plant.

An imposing monument has been erected at Jenkins to the memory of John G. Smyth, former manager of the Consolidation Coal Co. and founder of the coal towns of Burdine, Jenkins, McRoberts and Dunham, who was killed by a slate fall in a mine at Elswick about eighteen months ago. The monument was erected in a public park through contributions from thousands of company workers.

Two hold-up men who looted the Bank of Vico, Perry County, of a \$6,000 payroll of the Knott Coal Corporation, and \$8,000 of bank money, were captured a few miles from the town, riding the rods of a coal train. The country is so wild and passes are so few that there is not much opportunity for a thief to escape.

S. T. Ballard, of Louisville, official of the Liberty Coal & Coke Co., of Straight Creek, who has been spending the winter at Eau Gallie, Fla., was taken to Jacksonville, Fla., for an emergency operation for appendicitis. He was in a dangerous condition, but is reported to be improving.

The Louisville & Nashville R.R. has placed some contracts for its own coal supply with mines on its lines. One Louisville concern stated that it had obtained eastern Kentucky contracts at around \$1.75 a ton, but understood that business had been placed at all the way from \$1.65 to \$1.90 a ton for mine run in eastern Kentucky, and that some business had been placed at from \$1.85 to \$1.90 in western Kentucky.

MASSACHUSETTS

Sealed proposals for furnishing approximately 6,000 gross tons anthracite for use of the Commonwealth of Massachusetts in its various institutions will be received by the Commission on Administration and Finance, Room 315, State House, Boston, Mass., until 2 p.m., Monday, April 14, 1924, and then publicly opened and read. Copies of specifications and bidding sheet may be secured upon application to the commission.

NEW YORK

Shipment of coal contributed heavily toward the prosperity of the Erie R.R. in 1923. The increase of more than \$14,000,000 from this source and from the transportation of general merchandise was in a large measure responsible for the excellent results attained from operations in 1923, when net income after taxes and charges was \$8,435,272, as compared with a deficit of \$3,132,770 in 1922. After allowing for 4 per cent dividend requirements on the first and second preferred stocks, the company earned \$5.22 a share on \$112,481,900 common stock. The sole explanation for the increase in the item "Coal" was the fact that in 1923 the company's revenues were not affected by strike conditions like those in 1922. The income account for the year ended Dec. 31 last shows total operating revenues of \$132,978,455, as compared with \$106,874,103 in 1922. Operating expenses were \$108,070,145, as compared with \$100,101,523. After deducting sinking fund charges the company had a surplus of \$7,218,207 in 1923, as compared with a deficit of \$4,078,817 in 1922. Decrease of some \$3,000,000 in cash in the statement of assets on the company's balance sheets as of Dec. 31 last was more than made up by the decrease of more than \$6,000,000 in loans and bills payable. "Accounts and wages payable" decreased from \$17,081,700 in 1922 to \$15,357,309 in 1923.

The American Coal Co. for 1923 reports profits of \$1,112,691 against \$821,166 in 1922, after allowing for all operating expenses. After reserves for depreciation, depletion and other charges there was a balance of \$915,852, against \$639,765 in 1922. The 1923 balance was equal to \$18.46 a share on the 49,598 shares of \$25 par value capital stock before provisions for federal taxes, against \$12.90 a share in 1922.

The Louisville & Nashville R.R. in the year ended Dec. 31, shows net income of \$13,498,935 after taxes and charges, equal to \$11.53 a share on \$117,000,000 capital stock, against \$10.598,019, or \$14.72 a share on \$72,000,000 stock in 1922. Operating revenue was \$136,375,672, against \$121,138,840; operating expenses \$109,865,090, against \$99,604,496; dividends paid during the year increased to \$5,850,000, as compared with 5,040,000 in 1922. The company's surplus rose to \$7,427,833, against \$5,387,134 in the previous year.

OHIO

The Shores-Allen Land & Fuel Co., St. Clairsville, has been incorporated with a capital of \$100,000 to mine and deal in coal and coke. A general jobbing and retail business also will be done. Incorporators are Ethan E. Allan, Albert E. Clark, William Hickman, R. S. Fry and Louis M. Shores.

Stockholders of the Hocking Valley Railway Co., at their annual meeting recently at the Spahr Building, Columbus, elected the following directors: O. P. Van Sweringen, Cleveland; M. J. Van Sweringen, Cleveland; W. J. Harahan, Richmond, Va.; J. J. Bernet, Cleveland; C. L. Bradley, Cleveland; W. A. Colston, Cleveland; Thomas J. Davis, Cincinnati; Parmely W. Herrick, Cleveland; F. R. Huntington, Columbus; Otto Miller, Cleveland; J. R. Nutt, Cleveland; Walter L. Ross, Toledo, and J. B. Zerbe, Cleveland.

The Mid-West Coal & Mining Co. has opened an office in the Union Trust Building, Cincinnati, with R. N. Osborne, Jr., as district manager and H. K. Howard as assistant. Mr. Osborne formerly was sales manager of the Borderland Coal Sales Corporation, and previously was with the Smokeless Fuel Co., and the Glen Alum Fuel Co. Mr. Howard formerly was with the Black Diamond Coal Co. of Cincinnati, and for a short time was with the Old Dominion Coal Corporation as resident manager. A. F. Dietrick is the head and general manager of the Mid-West company, with general offices at Cairo, Ill.

The Central Fuel Co., of Cincinnati, has liquidated, according to a statement issued by its president, B. Lee Hutchinson. The company was started during wartimes to do a jobbing business, but for the past two years has been handling mostly the output of the mines of Mr. Hutchinson and his brother. Negotiations are said to be pending by which these, which are in the Logan County and Kanawha fields, will be taken over by a large Fairmount (W. Va.) corporation. James Hatch, of the Cincinnati office, has joined the forces of the Hutchinson coal company.

After nearly three years, the final record has been filed in the closing of the business of the Peerless Coal Co. in Cincinnati with the filing of the report of Charles T. Greve, referee in bankruptcy. This shows that the total liabilities were \$20,873 with assets realized of \$9,381, hence the creditors received \$8,610, or 41½ per cent.

Pickands Mather & Co. announces the removal, March 31, of its offices from the Western Reserve Building to the twentieth floor of the Union Trust Building, Cleveland.

The Crown mine, Rose Farm, which had been idle for several months, has resumed operations giving employment to approximately 300 miners. Several large contracts have been obtained by the owners.

PENNSYLVANIA

Indications are that the strike at the Vintondale Collieries, at Vintondale, will be prolonged for some time. District President John Brophy states that every man employed about the operations has joined the union, there being now 400 members in the Vintondale Local. From other sources this is denied. Evictions continue. Governor Gifford Pinchot has advised the evicted miners to resort to the courts to stop evictions, as, to his mind, the leases are perfectly legal. President Charles M. Schwerin, in reply to the Governor, said he could scarcely stop evictions now as the twenty families notified to vacate company property had already moved out. Mr. Schwerin declared that "when we find these occupants trouble makers, we feel that we are in the right when we ask them to leave, as we consider the homes the workers occupy just as much the property of the company as the mines, the pumps, fans or dynamos." Governor Pinchot notified company officials that he had sent a mediator into Vintondale to see what could be done to end the strike.

A \$46,000,000 program of hydroelectric development has been announced by the Penn Public System of the Pennsylvania Electric Corporation, which is erecting three dams and power stations as part of the program, on the Clarion River, in Clarion County. The plant is expected to be ready for operation by June. The project is known as the Piney Development. It was started in 1922 as the smaller of three projects on the Clarion which will cost \$28,000,000. The other part of the program takes in the Youghiogheny River in Garrett County, Md. There, 2,400 feet above sea level and "at the top" of the Alleghenies, the first of four dams and three power stations are under construction, at a cost of about \$18,000,000. According to officers of the corporation, each of the underlying companies is able to finance its developments through the sale of bonds and stocks. They include the Erie Lighting Co., Home Heating Co. (Erie), Warren Light & Power Co., Jefferson Electric Co., Du Bois Electric & Traction Co., Centre & Clearfield Railway Co., Johnstown Fuel Supply Co., Sykesville Electric Light, Heat & Power Co., Big Run Light, Heat & Power Co., Penelec Coal Corporation and the Venango Public Service Corporation group of nine others. Other participating corporations in the development of the system are the Clarion River Power Co., Eastern Land Corporation, Clarion Water Co., Youghiogheny Hydroelectric Corporation, Eastern Coal Corporation and the Penelec Water Co.

Thursday evening, April 24, has been set as the date for the banquet for the members of the Johnstown Mining Institute. State Geologist George H. Ashley, of Harrisburg, has been invited to deliver an address. Charles O'Neil, of Altoona, secretary of the Central Pennsylvania Coal Producer's Association, also will speak. Five hundred are expected to attend.

An analysis of the causes of accidents that, during the past five years, have cost Pennsylvania's mining industry the labor represented by approximately 16,000 men employed steadily through that period—80,145 man-years—has just been completed by the Coal Mine Section of the Pennsylvania Compensation Rating and Inspection Bureau. The analysis, comprising more than fifty tables and charts prepared under the direction of Rush N. Hosler, superintendent of the section, covers Pennsylvania's mine-accident experience during the seven years from Jan. 1, 1916, the time when the Pennsylvania workmen's compensation law went into effect. During this period there were 3,620 fatalities in the anthracite field and 3,003 fatalities in the bituminous regions of the state. The analysis covers these as well as the non-

fatal casualties. Contrary to the popular belief, the analysis shows, explosions in the mines are not the cause of the greatest number of accidents. Falls of rock and roof rank first among the causes of injury and death to the mine workers. Haulage accidents come second. The miner killed at his work leaves an average family of three children, and the average age of each dependent child is six years and thirty-four weeks.

Thomas Elliott, of Brownsville, president of the Lilley Coal & Coke Co., of West Brownsville, is making an extended tour of Europe. He will be away for several months.

A state charter has been issued to the Red Top Coal Co., Indian Head, with a capital stock of \$50,000. The purpose of the company is to acquire coal and coal lands and their operation. The incorporators are Ralph P. Barnard, 1420 New York Avenue, N. W., Washington, D. C., treasurer; Charles S. Harper, Philadelphia and George N. Ault, Ridley Park.

TEXAS

For the year ended Dec. 31, 1923, the Texas & Pacific Coal & Oil Co. reports a net loss of \$279,238 after depreciation, depletion, amortization and inventory adjustments. This compares with a net income of \$2,077,736, after depreciation, but before depletion, amortization, etc., in the previous year. After the payment of dividends there was a deficit of \$701,520, as compared with a surplus of \$1,233,175 for 1922. The gross earnings for the year were \$5,625,306, as compared with \$7,316,287 for 1922.

UTAH

The U. S. Fuel Co., of Salt Lake City, has contracted with Roberts & Schaefer for the complete installation of new steel tipples and screenings bins at East Hiawatha.

Nels R. Erickson, formerly general sales manager of the Premier Coal Co., has been appointed to a similar position with the Rock Springs Coal Co., of Ogden. Mr. Erickson has been in the coal business since 1912.

VIRGINIA

The State of Virginia has awarded a contract for 25,000 tons of New River pool No. 1 coal to the Lake & Export Coal Co., to be delivered over the Chesapeake & Ohio at \$1.95 net tons at mines. A contract for 35,000 tons of Pocahontas pool No. 1 was awarded to the Virginia Smokeless Coal Co., to be delivered over the Norfolk & Western at \$2.10.

The City of Norfolk has awarded a contract for 9,000 tons of navy standard Pocahontas coal to the Smokeless Fuel Co., at \$2.25.

WASHINGTON

Foreseeing less oil fuel competition with the decline of California oil production, the Pacific Coast Coal Co. is now developing two new mines near Seattle. One is the new Newcastle mine, now getting into its stride, and the other is to be called the Indian mine, at the village of Indian, in the Cedar River valley. This mine is expected to attain a production of 1,000 tons a day by Sept. 1. These mines are to replace the old Newcastle mine and the old Black Diamond mine, both of which are approaching exhaustion.

WEST VIRGINIA

The Thomas & Wilson Coal Co. will commence the development of coal territory on Cabin Creek in the Kanawha field in the near future, having leased about 515 acres on the west side of Cabin Creek from the Ohley Coal Co., subject to the rights of way of the Chesapeake & Ohio Ry. and the Virginian Power Co. and the surface rights of the Don Coal Co. The company is headed by John Oldroyd, of Upshur County. The lease runs for a period of 20 years, dating from March 6 and gives the Thomas & Wilson Co. the exclusive right to mine coal, make coke on the premises and to erect any necessary buildings. The lessee is to pay a royalty of 7c. a net ton except when coal is down to \$2 a ton or less, when a royalty of 5c. a ton is to be paid. From June 1, 1924, to Sept. 1, 1924, the minimum royalty payment is to be \$100 a month whether that much coal is mined or not, and thereafter \$2,400 a year whether the amount of coal mined would yield that sum annually or not.

The annual report of the West Virginia Department of Mines for the year ending June 30, 1923, just submitted to Governor E. F. Morgan, shows that 81,136,729 gross tons of coal and 823,912 net tons of coke was shipped over the railroads from West Virginia mines. Shipments by river totaled 1,097,277 tons, 925,830 tons of which originated on and was floated down the Great Kanawha and 171,447 tons was shipped on the Ohio River. This does not include the tonnage consumed by water craft and local river trade. There was no coal shipped on the Monongahela River and no coke was shipped either on the Kanawha, Monongahela or Ohio rivers during the year. The report of the department shows that during the year the average wage received by pick miners throughout the state for mining run of mine coal was 97c., which was an increase of 2c. over the price paid in 1922. Each pick miner produced an average of 1,237 tons, an increase of 126 tons over the fiscal year 1922. The average annual wage of pick miners (all pick miners included) was \$1,199.89, an increase of \$144.44 over that of 1922. The average selling price of coal shipped from the mines of the state was \$3.18 per gross ton, run of mine coal, an increase of 63c. a ton over that for 1922. Coke was sold f.o.b. at the ovens at an average price of \$7.14 per net ton, an increase over the previous fiscal year of \$1.23 per ton.

The Diamond Coal Co., of Fairmont is building a new steel Marcus tippie at Riversville.

WASHINGTON, D. C.

The U. S. Civil Service Commission announces an open competitive examination for Junior Engineer, mining, to fill vacancies in various branches of the government service at an entrance salary of \$1,860 a year. The examination will be held throughout the country on May 7. Full information and application blanks may be obtained from the U. S. Civil Service Commission, Washington, D. C., or the secretary of the board of U. S. Civil Service examiners at the post office or custom house in any city.

CANADA

A resolution calling upon the government to initiate a policy which would give to the Dominion an all-British and Canadian coal supply, was moved in the House at Ottawa March 31 by T. L. Church, Conservative member for North Toronto. Mr. Church's motion asked that a duty be placed on coal from the United States so as "to insure an all-British supply for Canada, and thus afford adequate protection to coal mined and coked under the British flag."

The Maritime Coal Co., operating mines at Joggins, for many years, has negotiated an agreement with the company's employees. The agreement is the same as that rejected by the miners of the British Empire Steel Corporation. The indications are that the miners of the Maritime company, while continuing with the United Mine Workers will refuse to recognize the Communist majority in the district who have repudiated the agreement.

The River Hebert pits will resume operations within the next few months, according to indication. A company is being formed to take over the mines, and all that is now necessary is to effect a wage and conditions agreement with the miners. The prospects are that the same agreement rejected by the miners in the district, by majority vote will be acceptable to the River Hebert miners. Indications are also that the miners employed in the Springhill mines will accept the so-called Barrett agreement. The Springhill miners are known to be out of sympathy with the Communist majority in the United Mine Workers and took no part whatever in the elaborate reception to J. B. McLachlan on his release from prison.

The Saunders Ridge Coal Co., Ltd., with head office at Calgary, Alberta, has been granted Dominion incorporation with an authorized capital of \$1,500,000.

The Liverpool Chamber of Commerce announces the formation of a company, including Sir Alfred Mond and representatives of other Welsh colliery interests, to install a complete breaking plant in Montreal to handle Welsh anthracite of the sizes required by Canadian trade. The plant will be ready to deal with shipments at the opening of this year's navigation season. In the first year the Welsh coal interests are expected to ship a minimum of 100,000 tons of anthracite to Canada.

Traffic News

C. & O. Buys Three Short Lines

The American Rolling Mill Co. announced the sale, April 1, to the Chesapeake & Ohio R.R. of the Ashland Coal & Iron Ry., a forty-mile road extending from Ashland to Seaton, Ky. The deal was said to involve approximately \$4,100,000 and was described as "cash." The deal was consummated in Cleveland, Ohio, by the Van Sweringen interests, which control the Chesapeake & Ohio.

Purchase of the Long Fork branch of the Baltimore & Ohio Railroad and the Miller's Creek line, both connecting with the Big Sandy division of the Chesapeake & Ohio Ry. was announced March 21 by the Chesapeake & Ohio. Both lines tap some of rich coal fields of Kentucky. The Long Fork line is about twenty-five miles long, and in its operation the Baltimore & Ohio was obliged to make use of the Chesapeake & Ohio's tracks from Martin to its own main line. The Miller's Creek road is little more than four miles in length, but it opened into fields which, on account of their geographical location, were regarded as belonging to Chesapeake & Ohio territory. The Chesapeake & Ohio, it is understood, has sought for several years to acquire these two lines. The purchase price was not made public.

Association Activities

Delegates attending the twentieth annual convention of the **Canadian Retail Coal Association**, in Toronto, on April 4 and 5, gave consideration to the problem of Alberta coal. The coal men pointed out a number of obstacles to economical distribution of Alberta coal in Eastern markets. Freight rates as arranged by the president of the Canadian National Rys. are prohibitive, and as the coal will not stand storing in the open air there is a problem of providing storage space and other facilities which would have to be faced. A crayon talk on "Coke and Its Manufacture" was given by F. E. Lucas, B.A., specialist of the Dominion Coal Co., and Major Charles B. Staats, director of the National Association, dealt with some of the problems and aims of the parent organization. The following officers were elected for the ensuing year: President, W. H. Smith, Owen Sound; Vice-President, F. A. Dunlop, Hamilton; Secretary-Treasurer, Bert Caspell, Brantford; directors, M. F. Cray, Guelph; T. E. Pratt, Peterboro; Fred Mann, Brantford; J. C. Fowlds, Oshawa; F. H. Marlatt, St. Thomas; G. F. Rogers, St. Catharines, and J. A. McLean, Wingham. A model of the Loree breaker, owned by the Hudson Coal Co., attracted considerable attention. C. D. Winter was in charge and in explaining its operation pointed out some of the problems of the mine operators.

Industrial Notes

S. A. Emery, former Eastern manager of the Dodge Manufacturing Co., has joined the sales force of the **Royersford Foundry & Machine Co.**, Philadelphia, Pa. He will sell the entire Royersford line, including Sells and Royersford bearings, hangers, couplings, collars and other transmission equipment. He joined the company March 1.

The **Semet Solvay Co.**, of Syracuse, N. Y., has contracted with the Roberts & Schaefer Co. for pneumatic dry cleaning tables for cleaning coke breeze at their Detroit operation.

Obituary

Charles Herr, proprietor of the Lackawanna Coal Co., in the city of Lackawanna, adjoining Buffalo, died in hospital on April 1, from injuries received from a falling coal conveyor in his yard. He was president of the Lackawanna Chamber of Commerce and otherwise prominent in business affairs. He was 53 years old and left a wife and eleven children.

W. C. Mullan, superintendent of the Continental No. 1 mine of the H. C. Frick Coke Co., at Uniontown, Pa., died at his home there on the afternoon of March 24. He was 70 years of age. Mr. Mullan was a native of Bradford, Pa., and at one time he was considered among the applicants for president of the Frick company. He was well known in mining circles in northern West Virginia, especially among those having connections with the coke belt. Burial was at Mount Pleasant, Pa., on Thursday, March 28.

Spencer H. Rhoads, auditor of the Rochester & Pittsburgh Coal & Iron Co., died at his home in Indiana, Pa., on March 28 of heart disease. His death was sudden, as he had attended to business during the day. He leaves a wife and daughter.

Howard Vernon McCardell, Cresson, Cambria County, Pa., coal operator, died at his home there on April 1 from burns received in a gas explosion in one of his mines on March 11. He was the son of Mr. and Mrs. James B. McCardell, of Cresson, and is survived by his wife, his parents and two brothers and a sister.

Stephen B. Jones, 69, of Chicago, father of Homer D. Jones, recent president of the National Retail Coal Merchants' Association, and for years in the retail coal business in Chicago, died March 23 at his home after a nervous breakdown.

Coming Meetings

American Welding Society. Annual meeting, April 22-24, Engineering Societies Building, 33 West 39th St., New York City. Secretary, W. M. Kelly, 33 West 39th St., New York City.

National Exposition of Coal Mining Equipment and Machinery of the American Mining Congress, May 12-17, Cincinnati, in conjunction with the annual meeting of the National Coal Association.

West Virginia Coal Association. Annual meeting May 13-17, Cincinnati, Ohio. Secretary, W. H. Cunningham, First National Bank Building, Huntington, W. Va.

National Coal Association. Annual meeting, May 14-16, Cincinnati, Ohio. Executive Secretary, H. L. Gandy, Southern Building, Washington, D. C.

Pennsylvania Retail Coal Merchants Association. Twentieth annual meeting and exposition, Commercial Museum, 34th and Spruce Sts., Philadelphia, Pa., May 22-23. Secretary, W. M. Bertolet, Reading, Pa.

International Railway Fuel Association. Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary-Treasurer, J. B. Hutchinson, 600 Michigan Ave., Chicago, Ill.

The American Society of Mechanical Engineers. Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

American Wholesale Coal Association. Annual convention, White Sulphur Springs, W. Va., June 3-4. Secretary, G. H. Merryweather, Chicago Temple Bldg., Chicago, Ill.

The National Foreign Trade Convention. June 4-6, Boston, Mass. Secretary, O. K. Davis, 1 Hanover Square, New York City.

National Retail Coal Merchants' Association. Annual meeting, Hotel Virginian, Bluefield, W. Va., June 4-6. Secretary, Walter D. Rogers, Transportation Building, Washington, D. C.

New Equipment

Current Relay Equipped with Self-Contained Ammeter

A line of overcurrent and directional relays equipped with a current-indicating element has just been developed by the Westinghouse Electric and Manufacturing Co. These relays differ from the standard CO and CR, overcurrent and directional relays respectively, in that they have self-contained ammeters which give a continuous indication of the current flowing in the circuit. They are designed for use where the relays are mounted on the front of a switchboard and where there is insufficient room to provide separate ammeters.

In addition to operating as protective relays, they indicate the current flowing through the circuit, thus showing that the relay is receiving current through its circuit and is in condition to operate if a short-circuit should occur.

The indicating element of this new relay consists of a thin copper disk mounted on a separate shaft and having its own jewel bearing and control spring. It is actuated, however, by the same flux which operates the main disk to close the contacts of the relay. This prevents the indicating element from operating when there is any trouble either inside or outside the relay that would prevent the main electro-magnet from being energized. This meter and

Directional Current Relay with Ammeter

Aside from protecting the circuit against any possible overload, this new relay gives a direct indication of the current in the circuit. This makes it relatively easy to set the relay for the proper current overload.

relay gives a visual indication of load variations and will show how the load builds up on the circuit.

Flow Meter Functions by Transformer Principle

A new type of electrically operated flow meter which works on the principle of an alternating-current transformer has been recently developed. This meter can be made indicating, recording or integrating to measure the flow of gas or liquid through a pipe. Owing to the electrical principle of operation the instruments can be placed

winding on a transformer. To supply this secondary current an increased current must flow in the primary which will be indicated on the ammeter.

The difference between the two currents will be a measure of the fluid flowing in the pipe line, as the height of the mercury in chamber A is a measure of the quantity. The current flowing in the mercury ring will be in direct proportion to its height. That is, a ring $\frac{1}{4}$ in. deep will have one half the current flowing in it that a ring $\frac{1}{2}$ in. deep would have, as the former has twice the resistance of the latter. Increasing the current in the secondary would cause proportional increase in

the primary current. The ammeter could be made to indicate the quantity of fluid directly by adjusting it so that with no flow in the pipe line, its needle would point to zero. Then calibrate it so that, as the mercury rises in chamber A, the increased current flow in the primary will cause the needle to point to divisions

on the scale representing the flow in the pipe.

This new meter is the product of the General Electric Co. and is not intended to supersede the mechanically operated flow meter of this company.

Electric Screwdriver and Socket Wrench

Quantity production methods demand the very latest designs in portable electric tools and their substitution wherever possible for the much slower and more costly hand operations. The

Motor-Operated Screwdriver and Wrench

Shop and repair work will be greatly facilitated by the use of this new machine, which is light in weight and easily controlled. Note the pistol grip and trigger switch, which greatly facilitates handling.

Black & Decker Manufacturing Co., Towson Heights, Baltimore, Md., announces a No. 3 portable electric screwdriver and socket wrench for heavy-duty production work. This tool, which weighs only 15 lb., has been designed particularly for driving very large wood screws, lag screws, and running up nuts on large bolts. The spindle is equipped with a positive clutch which automatically disengages when the forward pressure on the tool is released. The patented pistol grip and trigger switch is standard equipment. A universal motor furnishes the power and can be supplied for all standard voltages up to 250.

Instrument for Measuring Insulation Resistance

A new testing device known as the Junior Megohmer has recently been developed by Herman H. Sticht & Co., 15 Park Row, New York. Like other models of this kind made by the same company it combines a megohm-meter with a voltmeter. The instrument is one of the smallest of its kind, and is especially suitable where relative values of resistance are of more importance than very accurate measurements. It is a convenient instrument for inspectors because of its light weight.

The measuring system consists of a small but high grade D'Arsonval galvanometer, with a double scale gradu-

Testing Instrument with Megohm-meter and Voltmeter

This instrument is suitable for making high-resistance insulation tests. It is complete in that it has its own generator and is provided with a voltmeter and a scale for measuring resistance in megohms.

ated 0-20 megohms and 0-120 volts. Four binding posts are provided, thus giving the instrument two voltmeter ranges, 0-120 and 0-240 volts, in addition to the megohm scale. Operating instructions are mounted in the cover of the instrument and are always visible to the operator when the instrument is in use. A hand operated magneto-generator furnishes 110-volt pulsating direct current which serves as a source of potential for insulation measurements.

any distance away from the pipe line through which the flow is being metered.

The electrical element is a transformer with a primary winding which is connected to a source of alternating current of constant potential. Without any secondary load on the transformer, the only current flowing in the primary winding is that to magnetize the core and supply the losses in the core and coil. If a properly calibrated ammeter is connected in the circuit as shown, it will indicate this current.

On the secondary leg of the core is a fiber container made in two compartments—one, A, that surrounds the core, and another, B, that contains mercury but is in communication with compartment A. These compartments are connected on the opposite sides of an orifice in the pipe line through which the fluid or gas flows. With no flow in the pipe line the pressure in A and B will be the same, and the mercury is at a height so as to be at a level with the bottom of A. When there is a flow in the pipe line, a difference in pressure is created across the orifice, so that the pressure in A will be lower than in B, resulting in mercury being caused to rise into A to a height that will equalize the pressure between the two chambers. When the mercury rises in chamber A, it surrounds the laminated core and forms a short-circuited secondary winding of one turn.

This ring of mercury around the core is similar to a copper ring, except that it has a higher resistance for a given cross-section. In the mercury around the core a current will be induced just as in a closed secondary

Bad Work Never Pays

DOES the isolated plant pay? Only if it is well conducted and rightly equipped. That, in normal times, is true of almost any establishment. No one can persistently do the work wrongly and "get away with it." So perversely was the isolated plant slighted by its owner, starved, spurned, forgotten, that we wonder it so long endured. It was a marvel that purchased power did not come to the coal fields sooner. But today, the isolated plant at the coal mines is looking up. The Nason plant to which reference is made in last week's issue is a case in point and there are many others. Rightly planned, well executed, and properly operated, the isolated plant burning mine refuse survives and deserves to survive.

Making One Prosper Where Two Died Before

MOST of the mining companies are over extended. A few mines well worked and better equipped are better than many mines working slow time and inefficiently. A well-pruned tree grows more greenly than one that is limby. Some of the companies are doing a pruning job this spring and shutting down certain of their mines, and the evidence is that it is not being done any too drastically. One mine with conveyors, machine loaders and careful supervision will produce as much as three without these assisting factors and make a big profit into the bargain. A great man is he who makes two blades grow where one grew before, but greater is he who makes one mine bring in big dividends where before were two headed for a knockout blow by the auctioneer's hammer. The years 1924 to 1927 may set many operators into a way of thinking more clearly. The motto of these years will be "Better rather than more mines."

Talk Mines, Not Politics

FOR many years executives have been prone to talk politics rather than mines. A new era seems in prospect. We shall talk mines rather than politics. We seem likely to interest ourselves for a decade at least in new methods and new machinery rather than in log-rolling and lobbying. Conditions forced the latter on us whether we would or not. We were attacked and threatened. We were bullied and cajoled, and we could not mind our proper business even if we would. But that is over now, thank goodness. Even the U. S. Coal Commission is gone, and the politics of industry is over. We can leave the cracker barrel, the soap box and the picket fence and go back to the mines.

As a symbol of the new spirit, the operators, their engineers and executives are going to meet at Cincinnati—under the auspices of the American Mining Congress, mind you—to talk lower costs per ton, not the

Capitol, nor the President, the Fuel Administration, the Attorney General or the Governor of Pennsylvania, but, what is more important for all mining men, just plain and everyday mining and how it can be bettered. It takes almost a wrench to get back to business, and away from Washington. But it's worth while. We never mined much coal or did it cheaply, so long as it was being mined at Washington and Indianapolis. The Washington miners are little better than those at Moscow.

Selling Coal in Kilowatts

STUDIES by the experts under the Department of Commerce show that after 1930 there probably will be no growth in the use of northeastern hydro-electric power. This may be regarded by mine owners as a hopeful sign, and indeed it will make for increased prosperity, probably for commercial-mine owners and certainly for the industry. One must distinguish between the two because they are not necessarily the same. Indications tend to show that the power plants are rapidly acquiring mines and when they do they turn all the coal to their own properties and cease to absorb the byproduct of coal mining—slack.

What will be the fate of the commercial-mine owner if he can sell only domestic coal and has no market for steam sizes? Will it be to the advantage of the country and the custom-mine owner if the slack must be wasted or be a drug on the market? The metallurgical plants are already almost completely supplied with mines. The power plants and gas companies are coming into the same class, and little place is left for slack when these three are completely satisfied. When this tendency has become a universal condition, the coal operator will be back in the same place where he lay before the mechanical stoker was introduced.

Consequently, it would seem desirable that coal companies organize their own power-manufacturing companies or manufacture power themselves—running their stations, not with their entire product, but with their fine coal only, sending the coarse coal to the domestic market. In this way they will put each product to the purpose for which it is best adapted, and they will prevent the power, metal and gas companies from closing out their market for slack.

The field is not yet so completely filled that there is no room for starting this enterprise. Probably the mining companies will not need to merchandise power. They can put it on the busbars and leave to others its transmission and marketing.

The right place to manufacture is at the mines except where the distances are great. Mr. Hoover's survey shows that it is cheaper for Cleveland, which is 125 miles from the coal field, to get electricity from the mines than to generate it with coal transported to the city. The cost of delivered energy per kilowatt-hour is 6.7 mills, whereas the cost of energy on the

same basis generated by coal at Cleveland is 7.0 mills. At Baltimore, power transmitted from the mines 275 miles will cost 7.4 mills whereas power generated at that city will cost 7.45 mills.

At Philadelphia and New York, which are 350 and 425 miles distant respectively, it is cheaper apparently to generate at the city than at the mines using coal in both places as the source of power, but the difference at New York is only 0.6 of a mill, a quantity that might easily be offset by the use of inferior coal at the mine and other conditions. All this is dependent on a sufficient life being provided at the mine to keep the plant working for as many years as might be expected of the city plant without the necessity to ship in coal.

Two factors, however, militate against the conclusions given. One is that if the mine is to be used both as a source of power and as a source of domestic coal, it will either not have the necessary life or will have to be aided by railroad service. Two mines may be needed instead of one and an additional cost for transportation to the plant by railroad, mine track or conveyor will be incurred. This may be met, however, because the price of coal is estimated at \$3, which is high where the coal used is not the whole coal output but what is regarded as an inferior product. The average mine would be glad to get half that price for screenings.

A second consideration is that as the plant is at the mines, it is subject to the risk of strikes and possibly in case of a strike it might be hazardous to bring in coal from other mines to sustain operation whereas the plant in the city can use any coal that is on rails or on water, and so can weather the storm.

This difficulty is not preventing central stations from being erected at coal mines and should not prevent the mine owner from building such a station. When all the stations are tied together, hydro and steam, partial provision will have thereby been made for the exigencies of strikes. In any event much of the sale of power will be local and a strike will reduce the local demand for power greatly. Hence, failure of supply will occur at the same time as a failure of demand and no one will suffer.

Our Labor Exodus

IN METAL mines it has been customary to work the plant or some section of it at the full force or not at all. Restriction of output meant closing down units and not, as a rule, running a few days a week. In consequence, when a lull came in the market, a number of metal miners had perforce to move. Most of them went into other industries and many of them did not return. This kept the number of men in the metal industry normally below saturation. In the bituminous coal industry, the miners have worked in slack times only a few days each week, and when business became brisk there were always more men on hand than were needed to fill the tonnage requirements of the country.

Today, large concerns in the bituminous coal industry are taking a leaf out of the metal industry's book. They close down some mines and work the others intensively and at greater advantage. Fewer men are displaced, however, than in metal mines because the miners not being paid by the ton are engaged in larger numbers than actually needed and are given a place but only an inadequate supply of mine cars. They work

more nearly every day than in past years of depression, but do not get so generous an opportunity as they might to produce coal when they do work.

On the whole, however, the men are leaving the industry and the proposed car-rating plan if adopted will prevent their return, for the old mines when reopened will run less intensively than the mines that have continued working and will afford less opportunity to returning men. It is probably just as well. When all the mines are short of men, the new mines will have less chance to open, and the older mines which have the men will work more steadily. The miners also will profit by getting steadier work. That will make for greater contentment and give less time for that factional activity which breeds strikes.

Time for Lewis to Retire?

THERE have been indications for some time that President John Lewis of the United Mine Workers was diligently seeking a new job. It has long been known that he would like to succeed to the power and prestige of Samuel Gompers, for a quarter of a century head of the American Federation of Labor. Lewis was audacious enough to make an open bid for Gompers' office at the Denver convention of the Federation—and lost. So he settled back to wait; for Mr. Gompers is full of years. Since then it has been rumored persistently around Washington that Lewis was in a receptive mood toward a government appointment of some kind, though he has never been offered one publicly.

And now comes K. C. Adams, everybody's friend and a sort of unofficial publicitor for Lewis, suggesting that at the election next autumn the international President would make a pretty good running mate with Calvin Coolidge on the Republican ticket. In two interesting pages on the subject in a recent issue of his magazine published in the shadow of United Mine Worker headquarters at Indianapolis, Mr. Adams sets out a full trip load of reasons why Lewis would make a good candidate and wants to know "how that sounds."

It sounds to us very much like a feeler by a union leader who never has taken a backward step and who fears that he is going to be compelled to take one unless he sidesteps it. Lewis has led the union miners to a high pinnacle of power through a period extremely conducive to that sort of upward progress. And now he has pitched the union camp on that pinnacle for a three years campaign at a time when the rigors of that pinnacle promise to be severe for unionism. Attempting to hold out is going to be so costly in blood and treasure that the position may prove untenable. Somebody may have to direct that union army of miners in a strategic retreat of a few steps.

Mr. Lewis has never led such a maneuver. But he is a strong man and resourceful. He has proven himself a sterling leader of miners in periods of success. Now let him prove himself that greater man—the sterling leader in times of adversity. There are many serious problems for the United Mine Workers to meet during the coming three years. They need a man like Lewis to help solve them. Their sane and proper solution will be essential to the well being of the whole coal industry. They should not be solved for the Mine Workers by some "nit wit." Lewis should stick to his army—and anyway the Republican party and the people are not demanding his services as a candidate.

Reinforced Tippie, No. 12 Mine, O'Gara Coal Co.

"Build Everything of Concrete" Is O'Gara Policy

Tippie and Rescreener Cast Monolithic and in One Unit—Concrete Also Used in Shaft Bottoms, Roof Arches, Mule Stables, etc., Underground—Concrete Haulageway Roadbed Under Test

BY RALPH D. BROWN
General Superintendent, O'Gara Coal Co.
Harrisburg, Ill.

A COAL mine should be considered as a wasting asset with a definite and limited life. The designing engineer planning the plant may intelligently choose his materials of construction in accordance with this idea, provided no other reasons overbalance that consideration. Other factors that may affect the decision as to what materials shall be used are: (1) Availability and adaptability of the material to the proposed design, (2) first cost, (3) cost of maintenance, and (4) statutory regulations. The geographic location of the plant and the availability of any material at a reasonable price may be the determining factors, but in Illinois, the state law fixes definitely the type of construction; that is, it must be fireproof—and consequently of either brick, concrete or steel.

After weighing all considerations in the balance, including ultimate economy, the management of the O'Gara Coal Co. operating at Harrisburg, Ill., has chosen concrete as being best suited to the conditions found in that locality. At Mine No. 12 it has constructed and put into successful use a monolithic concrete tippie and screening plant and at other operations it has built concrete shaft linings, overcasts and stoppings, haulageways, arches for roof support, mule stables, fan houses and various types of surface build-

ings. The results obtained have been entirely satisfactory. When the rebuilding of the surface plant of O'Gara Mine No. 12 was under consideration, fabricated structural steel was quoted at \$125 per ton, and deliveries could be made only in from six to nine months, whereas cement could be had for \$2.80 per barrel, with immediate delivery. In addition, the company carried a construction force trained in concrete work. Concrete was therefore chosen as the material, and the design of the various structures prepared accordingly.

CANNOT ESTIMATE STRESSES IN A HEADFRAME

Many practical builders have considered concrete ill adapted to tipples and structures of like character because of its tendency to vibrate. They feared that stresses resulting from such vibrations might eventually disintegrate this material. In the tippie designed for Mine No. 12 vibrations were reduced to a minimum, and at the same time the bond between the steel and concrete was given due consideration where it was deemed probable that vibration might be expected.

It is not possible to measure accurately or even assume the stresses existing in an up-to-date tippie structure, hence a truly economic design cannot be made. It is better to be safe even at the expense of a possible

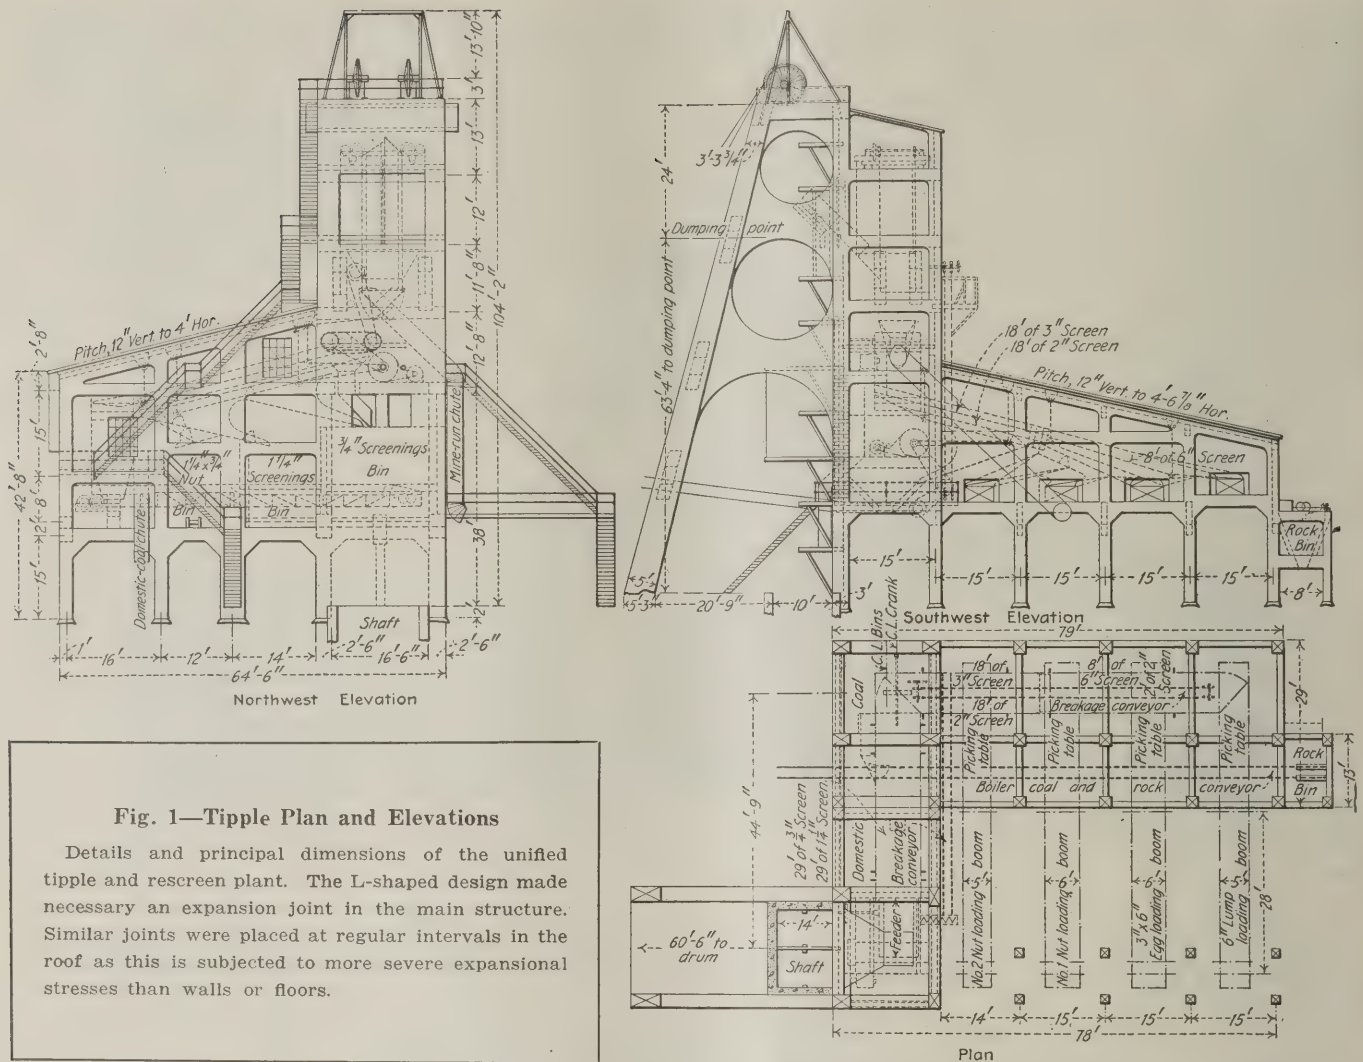

Fig. 1—Tipple Plan and Elevations

Details and principal dimensions of the unified tipple and rescreen plant. The L-shaped design made necessary an expansion joint in the main structure. Similar joints were placed at regular intervals in the roof as this is subjected to more severe expansional stresses than walls or floors.

surplus of material, for if the structure is too light the vibration will be excessive, causing eventual weakness and disintegration.

Referring to the plans of the concrete tipple, Fig. 1, it will be evident that the coal is prepared in more sizes than is generally attempted in a single unit. For this reason the structure housing the preparation equipment is more extensive and complicated than usual.

This plant provides for the sizing, preparation and loading of seven sizes of coal in one continuous process with a minimum of labor and equipment. Concrete bins, which have a combined capacity of 450 tons, are built as a monolithic part of the tipple and not only provide storage capacity but also facilitate the loading of the three smaller sizes of coal on one track. Picking tables and booms for loading railroad cars are provided on four additional tracks. The preparation equipment is entirely modern and adequate to handle a capacity output of 3,000 tons in eight hours. The screens are arranged in two units and protected from overcharging by a grizzly feeder, which is itself a screen, removing all coal less than $\frac{3}{4}$ -in. diameter before discharging its burden onto the shakers. The primary screen is constructed as a single-section, double-deck unit. This removes all coal less than $1\frac{1}{2}$ -in. diameter and passes the remaining lump to the secondary screen which extends at right angles to the first. The primary screen sizes all the coal under $1\frac{1}{2}$ -in., discharging each size in its respective bin. The secondary screen has two sections, is double-decked, and receives all coal above

$1\frac{1}{2}$ -in. diameter, regrading it and discharging the four sizes thus made onto four picking tables where hand picking assures a clean product.

Any breakage occurring after the coal has been sized is taken by a special conveyor to the primary screen where it may be re-sized. Refuse picked from the tables is conveyed to the refuse bin, and coal containing small quantities of impurities is delivered to a conveyor and taken direct to the boiler plant for fuel.

Reference to Fig. 2 will show that the equipment prepares all the commercial sizes without a separate re-screening plant. Such an arrangement requires shaker screens of more complicated design than are commonly employed and a housing structure adequate to resist all the vibratory stresses due to this more concentrated system of operation. Apparently reinforced concrete furnishes a material well fitted to satisfy all requirements of such a structure.

A foundation capable of carrying the enormous weight of a massive concrete structure is not always available near the surface. This in itself may form a limiting circumstance that would make the use of concrete impracticable. At Mine No. 12 a hard shale rock was found at a depth of only 22 ft. All footings of the main structure were accordingly carried down to this stratum and made of sufficient size so that no bearing stress was greater than 6 tons per square foot. The excavation for the foundation footings was made in an open pit by a crawler crane operating a clamshell bucket. The pit was made of ample size to insure that

no caving would block the required section, and the concrete was poured into forms which were removed as soon as possible so that the clamshell could fill behind the foundation.

Provision was made for carrying the enormous weight concentrated at the mouth of the shaft by lining the walls of the shaft for a width of 3 ft. to a depth of 35 ft. at which elevation solid strata were reached. Here a spread footing 5½ ft. wide was notched into the rock. This ties into the concrete end walls of the shaft by reinforcements of 60-lb. relaying rails set horizontally and vertically with 1-in. steel rods placed 12 in. apart. At a depth of 40 ft. an additional spread footing was provided and tied into the footing above by steel-rail reinforcements set both horizontally and vertically on 12-in. centers.

It is not possible within the limits of this article to go into the detail of the general design of the main structure, but a general idea of it can be obtained by reference to Fig. 1. The detail plans of the reinforcing have also been omitted for lack of space. Special care was taken to provide ample ties and bonds for all reinforcement rods in the various structural members.

Another interesting feature of this installation was the method by which the steel members were anchored to the mass of concrete. For example, the steel bunnions that hold the guides are built-up members riveted

Fig. 3—Concrete Archway Through Fault

Passage through this 30-ft. downthrow was originally roofed with steel timbers. These, however, could not withstand heavy rock falls and upkeep was costly. This archway, 12 ft. wide and 75 ft. long, was built for \$27.50 per lineal foot. It has proved entirely satisfactory.

to steel channel anchors projecting from the concrete a distance sufficient to make a strong gusseted joint. This construction was used so that any serious displacement or bending of the steel bars through accident readily might be repaired without injuring the effective anchorage in the concrete.

The main structure being L-shaped an expansion joint was provided at the juncture of the two sections so that either can expand or vibrate without danger of rupture. This expansion joint is located where the planes of vibration meet at right angles. Additional expansion joints were placed in the roof at 40-ft. intervals. With these exceptions the structure is a monolith. The additional expansion joints in the roof were provided to absorb the relatively excessive expansion and contraction of this part of the structure.

BUILT TO SUSTAIN ABNORMAL LOADS

The head structure of the hoist tower was designed with special care, so as to provide for any unusual stresses that might be caused by the lodging of cages in the shaft. Four built-up, steel-plate girders 3 ft. in depth anchored to the concrete at both ends carry the sheave wheels. All other structural members (except those supporting walkways) are of reinforced concrete.

The beams supporting the shaker screens, weighing from 15 to 30 tons each, will be subjected to continuous live loads of measured intensity. Accordingly they are constructed with ample reinforcement and of such a size as to withstand the calculated stresses.

The shaker screens are driven by connecting rods from steel crank shafts set on piers cast monolithic with the floor and outside walls of the building. The entire tippie equipment is electrically driven. Remote-control equipment makes it possible for one man, conveniently located, to manipulate efficiently the entire

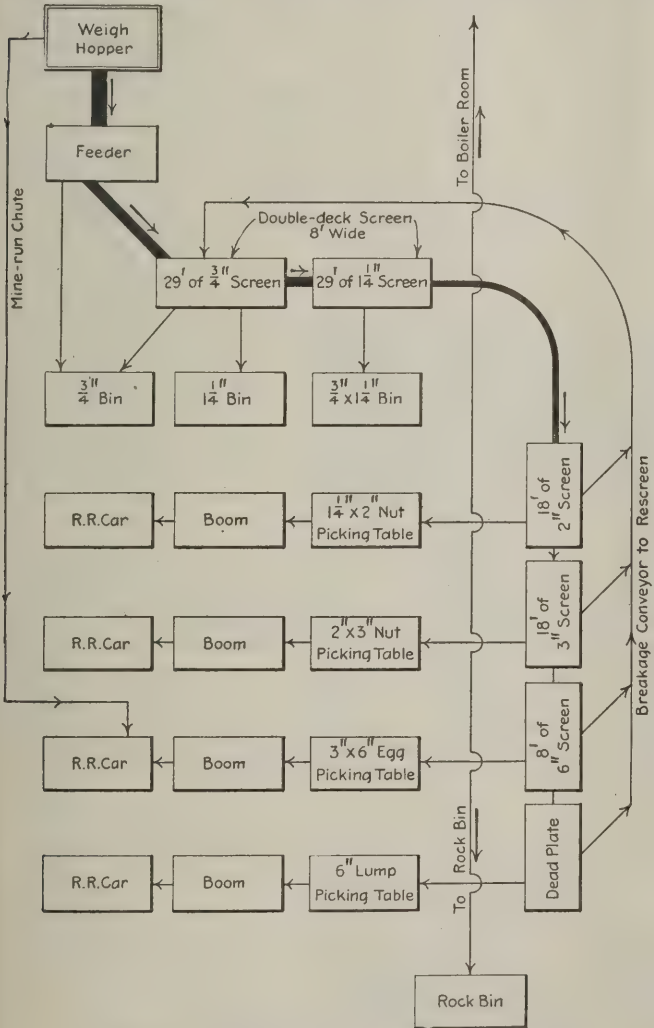

Fig. 2—Flow Sheet of No. 12 Tippie

By the use of bins the three small sizes can be loaded on a single track. The four other sizes are loaded each on its own track. The undersize goes back to the rescreen to be reprepared. The worthless material taken from the picking table goes to the rock bin. The better class of bone goes to the company's boilers.

FIG. 4

Concrete Roadbed on Main Haulageway

Tired of spending from 50c. to 75c. per lineal foot each year for maintaining haulage roads laid on wooden ties, the O'Gara company built this 300-ft. section of concrete roadbed in May, 1923, to test the possibilities of such a road. The first cost was \$2.50 per foot but thus far results have fully justified this expenditure.

system. In fact the arrangement of all machinery is correlated to the general principles of the design.

The construction plant employed in building Mine No. 12 was similar to that used on any ordinary large concrete job. The materials were unloaded and placed conveniently by a gasoline crawler crane. The concrete was mixed by an electrically driven batch mixer of 14-cu.ft. capacity located centrally at the foot of a 120-ft. hoist tower. After mixing, the concrete was discharged into a $\frac{3}{4}$ -cu.yd. bucket raised in the tower by a small steam hoist, dumped automatically and shot to place by gravity.

Concrete was made from portland cement, river sand and crushed rock in the proportions of 1:2:4. In the foundation the mixture was 1:3:6 and some large rocks 12 to 18 in. in diameter were embedded in the mass structure of the foundation. The reinforcement consisted of deformed bars and discarded mine hoisting rope. A sufficient force of carpenters was kept on the ground so that the pouring operation was practically continuous, thus preventing the formation of joints that might result in a future line of failure. Forms were not removed until the concrete had aged at least three weeks. Inasmuch as this work was done during the summer months of June, July and August, the concrete was well cured before any great stresses developed.

The mine roof in Saline County is comparatively good but a tight seal or stopping is sometimes difficult to build. The gray shale roof contains sufficient lime and other chemically unstable elements to disintegrate under the action of fresh moist air. Roof fracture is definite along certain planes, and disintegration crevices may extend well up into the strata. Consequently a seal to be tight must of necessity be made strong.

A plain concrete stopping is highly effective and satisfies the conditions when safety and fireproofness are essential, its only drawback being high first cost. In the mines of Saline County at the present time a hollow-tile stopping, plastered with stucco on one side is ordinarily employed because of its comparative cheapness and durability. When the roof is unusually bad a concrete seal is built. In closing off old workings this

seal is built double. A stopping of this character is composed of two walls from 6 to 10 ft. apart, filled in between with clay or sand. This affords a relatively tight seal having great strength and adaptability to any stresses that eventually may reach it from subsiding strata.

If the mine roof is badly faulted and at the same time subject to chemical disintegration through the action of fresh air, expensive timbering of some kind is necessary. Under ordinary conditions concrete is the best material to use in roof sustention. As there has been little need for systematic and regular artificial support of roadways in the mines of this locality, concrete has not been much used for this purpose. As a general rule the shaft bottom is secured by one of two methods, both satisfactory. The more usual plan is to erect substantial concrete walls along the entry sides and span the roadway between them with "I"-beams supporting either wood or steel laggings. The cost of such timbering will range from \$15 to \$30 per lineal foot of entry. The other plan is to use a concrete arch.

Fig. 5—Details of the Concrete Roadbed

Longitudinal rather than transverse members here afford support to the rails, the cross-members serving chiefly as ties to prevent spreading. As the bottom was fairly soft and could be cut without difficulty under the rail, trenches were excavated for the reception of the concrete. Consequently no forms were necessary for casting the supporting stringers.

This latter method affords the most permanent and serviceable of roof supports for mine bottoms, but the excessive first cost often renders this type of construction prohibitive. With the scale of wages now in force throughout the Central Competitive Field, the cost of an entry 18 ft. wide arched with concrete 12 to 18 in. in thickness will be from \$30 to \$45 per lineal foot.

In the accompanying illustrations Fig. 3 shows a vaulted airway through a 30-ft. downthrow fault. Before this arch was constructed large falls of rock, which the steel roof supports were unable to withstand, frequently had caused the steel timbering to fail. The archway shown is 75 ft. long, 12 ft. in width and cost \$27.50 per lineal foot. This cost included the filling in of all space above the arch with slate pack walls to prevent future falls of roof. No reinforcing was used in this arch and the concrete was placed in 15-ft. sections, forms being moved ahead after each section had been completed five days.

Timber available for mine use in southern Illinois is inferior in character, and its life is consequently limited. A tie placed in the motor road under ordinary conditions has an average life of two years. Such ties cost from 25 to 40c. each, f.o.b. mines. On main-haulage roads renewals are frequent but as they are necessarily made during operation of the mine their number per shift is small. The cost of such renewals will run from 75c. to \$1 each, including both labor and material, or approximately 60c. per foot of track. Adding to this the cost entailed by derailments and other incidental track expenses, we find that a motor road laid with heavy steel will cost annually from 50c. to 75c. per foot of track.

In an effort to reduce this maintenance expense, a 300-ft. concrete section of locomotive road was designed and built at Mine No. 10 during May of 1923. This piece of road was laid as a test to determine the use-

fulness of this type of construction for mine service. The conditions where this strip of road was constructed were ideal, as no water was present and the bottom was soft enough to be trenched for the laying of the concrete stringers underneath the rails. If it had not been possible to trench the bottom, the necessary forms for the concrete would have slightly increased the expense. This road as completed cost \$2.50 per foot.

Since the construction of this track the traffic over it has consisted of a 10-ton locomotive drawing from twenty-five to thirty cars, the gross weight of each being slightly over three tons. The locomotives average two trips per hour. To date, the results secured have been entirely satisfactory. No disintegration of the roadbed can be detected, nor has any disadvantageous condition developed that can interfere with future operation. A concrete roadway can only be constructed profitably on main-line or permanent haulage where no revisions of alignment or level are ever likely to be needed, for it is obvious that such a roadway once constructed is extremely difficult to alter or renew. However, given such conditions of permanency the use of concrete is well justified, for such a roadway if properly constructed will last as long as the mine.

The management of the O'Gara Coal Co. has found it necessary to construct several mule stables underground, and, taking into consideration the provisions of the mining law, it decided to build them of concrete. The stables so constructed are absolutely fireproof, safe, and easily maintained. All individual mangers, water troughs, partition posts and floors are cast monolithic and reinforced with small steel rods. Roof supports are also of concrete, as are also the side walls which seal off all coal or inflammable material.

Fig. 7 shows the design of one of these stables. Its arrangement is convenient and ample space is provided for each animal to rest in comfort without crowding.

FIG. 6

Concrete Stable

Three underground stables like this erected in 1917 have not cost one cent for repairs and have been comfortable enough to increase appreciably the efficiency of the mules. Sidewalls are 36 in. high surmounted by heavy wire netting allowing ample circulation of air. Mangers and feedboxes are also of concrete. Note the complacent expression on the face of Mr. Longears! This alone speaks volumes for the excellent sanitation of this underground stable. The law requires that all underground stables be made fireproof. The walls being of coal are lined with concrete.

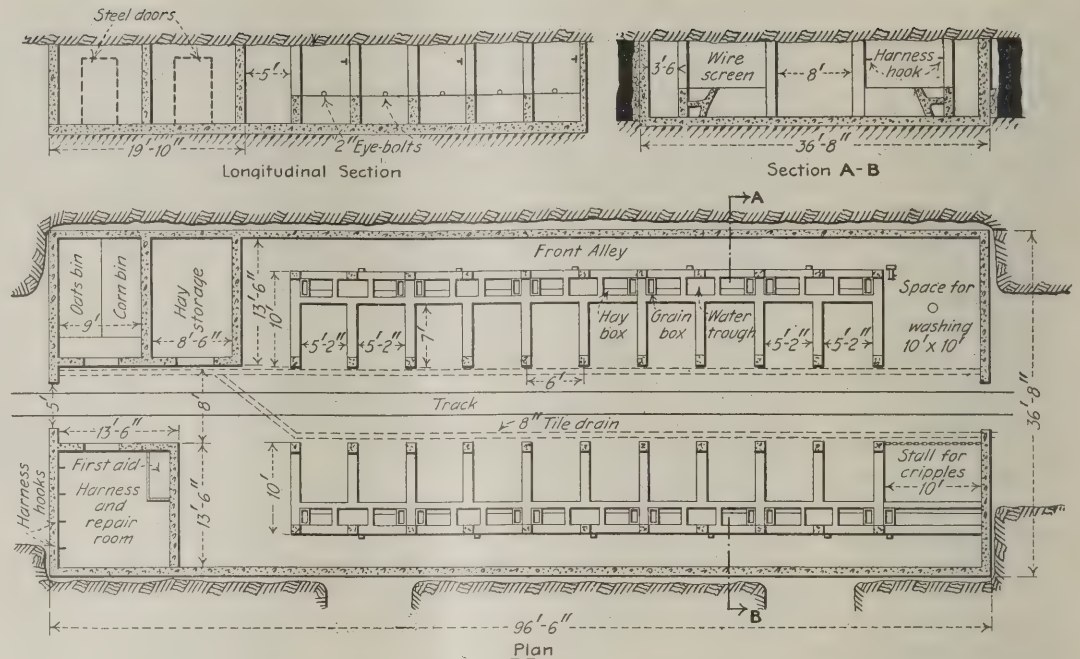

FIG. 7

Underground Stable

This shows the chief details of construction. These of course may be altered in any installation to suit any local conditions peculiar to the particular locality in which it is built. The chief essentials in addition to good drainage are ample room for each animal and adequate ventilation.

With a stable thus arranged it has been found possible to reduce the expense of keeping mules and at the same time greatly increase their efficiency.

Again referring to the design, it will be noticed that the partition walls of concrete between the stalls are not over 36 in. high and that the space from the top of the concrete to the roof is partitioned by heavy wire screen. This allows ample fresh air to circulate throughout the stable, affording the animals that adequate ventilation which is requisite for good health. Three of these concrete stables which were constructed in 1917 have not cost a cent for repairs in seven years.

Within the past four years the O'Gara company has recased with concrete six shafts that originally were timber-lined. Some of these shafts had been retimbered in the preceding six years and yet were found to be unsafe because the timber had decayed. The lining accordingly was replaced with concrete. In addition the company has sunk a 12 x 8-ft. air shaft, 400 ft. deep, lining it with concrete throughout.

There has been some discussion and more or less question as to the advisability of lining downcast shafts with concrete as in some cases the lining has disintegrated, its usefulness being practically destroyed in a

short time. All the concrete-lined downcast shafts in the vicinity of Harrisburg have proved entirely satisfactory although large quantities of alkaline water and frequent freezing and thawing during the winter months make conditions severe. Experience with concrete in this field therefore has demonstrated its usefulness as a material for shaft lining and practically all shafts in southern Illinois are so constructed.

The loss of any unit of the mine plant by fire or by disintegration shuts down the entire operation at least temporarily with a consequent commercial loss. This is especially true of the more important units, such as the fan, engine and boiler houses and the preparation plant. For this reason concrete has been adopted by the O'Gara company as the best material of construction for buildings of this character. It has been demonstrated that with concrete such buildings may be constructed at an equal or lower cost than with any other fireproof material. By this means also insurance premiums may be reduced to a minimum if not practically eliminated and the general overhead decreased.

Furthermore it has been found profitable to construct concrete smokestacks, as may be seen in the headpiece.

FIG. 8
Concrete Fan House

It was found that, considering the cost of labor, no other fireproof material could be used as economically as concrete for the construction of buildings as vital to operation as fan-houses. Incidentally concrete construction of top works appreciably cuts down insurance costs. If one important unit of a plant is destroyed by fire or accident the whole operation is closed down till it is repaired. Consequently it pays to build every part substantially.

Quantity of Timber Used in Soft-Coal Mines and How Much Will Be Needed in Future*

About 0.3 Cu.Ft. for Each Ton Produced—As Other Fuels Fail Bituminous Coal Must Gain—Stable Per Capita Consumption Probably Will Be Reached About 1960

BY NEWELL G. ALFORD
Pittsburgh, Pa.

ONLY with difficulty can forecasts be made of the future consumption of timber in bituminous coal mines, for no records are available of sufficient scope to enable us to determine the present timber requirements of the industry. The data on which this

Fig. 1—Past and Estimated Future U. S. Population

From this curve it would appear that the saturation point will be nearly reached by the close of the present century but will not be fully attained until the year 2100 A.D.

survey is based was obtained from plants where records are being kept and from some operators who collected the information for this survey. To these have been added composite figures for the continental area of the United States collected in 1905 and 1919† and for central and western Pennsylvania and for Illinois in

*Paper presented before the meeting of the American Institute of Mining and Metallurgical Engineers held in New York City in February, 1924.

†Forest Service Circular 49, U. S. Dept. of Agriculture (Timber used).

1922.⁴ The result, representing slightly over 928,000,000 net tons, is shown in Table I. Some of the companies furnishing data were unable to segregate the timber into the various purposes for which it was used but for those who did, Table II shows the board feet of posts and cross-bars used per ton of coal mined and what percentage of the total timber consumed was employed in roof support. The wide variation in quantities of timber consumed per ton of coal mined is due to differing mining conditions and to the variation in the quality and strength of the timber.

Fig. 1 shows the past and estimated future population of the continental area of the United States to its

Fig. 2—Past and Future Gas and Oil Production

These curves show not only the past production of gas and oil but their estimated future production as well. Both of these fuels have been reduced to their coal equivalent.

†Reports of Investigations, U. S. Bureau of Mines, Serials Nos. 2465 and 2546, April and November, 1923.

New Mexico	Raton	3 Seams	6.35	90.6

The curves showing the expected production of all coal and of bituminous coal, Fig. 3, take into account the future recessions in the railroad and industrial use of oil fuel as its supply is curtailed and the consequent increase in demand for coal as oil prices advance.

Concerning the oil production shown in Fig. 2, it should be stated that processes already are developed which will enable the refiner to triple the extraction of gasoline from fuel oil at a relatively small increased cost. Only the added expense prevents these methods from being used. This will decrease the quantity of fuel oil available. Furthermore, the supply of available

Fig. 4—Trends in Bituminous-Coal Production and Timber Consumption

These curves are practically identical except that they are drawn to different ordinates. In other words, 3.71 board feet of timber are allowed for each one ton of bituminous coal produced.

fuel oil will diminish with the certain enormous increase in the use of gasoline by automobiles. As the shallower fields approach exhaustion the costs entailed in sinking and operating deeper wells will increase, and sooner or later the United States Navy will discount its future need for conservation of fuel oil and secure legislation restricting its use to government purposes. With these factors affecting oil production and consumption, it is believed that the demand for coal and its consequent increased production because of the diminished supply and higher price of oil will rise at least as rapidly as it declined.

Increased efficiency in making electric power, and its wider and more efficient application will restrain, to an extent, the production of coal per capita, as shown in

Fig. 5—Heavy Timbering on Main Haulage Road

A scene in an anthracite, not a bituminous, mine. Over twice as much timber is used in the production of a ton of hard coal as is consumed in the mining of an equal weight of bituminous coal. When it is considered that mine timbers on the average last only about 3 years, it is not surprising that the mine timber costs are high.

Fig. 6—Growing Mine Timber on a Reserve

Some of the larger coal companies have already started reforestation of cut-over areas. It requires about 15 yrs. to grow a log suitable for a mine prop. In the future many coal companies must produce the pit lumber they consume. This reserve is owned by the Kingston Coal Co.

the curve of Fig. 3, the expected stabilization of this quantity taking effect within a decade or so after 1950.

When Is Electricity Safe?

Sliding Fits and Their Dangers in Permissible Equipment—Can a Machine Perfectly Fitted Electrically for Work in Gas Cause an Explosion?

EITHER alternating or direct current at 110 volts constitutes a shock hazard; even low-voltage circuits of high amperage may ignite methane. Consequently, said L. C. Ilsley of the U. S. Bureau of Mines at a recent safety conference in Pittsburgh, Pa., care must be taken even with circuits of the voltage indicated. Many fire hazards arising from electrical causes can be eliminated by good insulation.

In discussing Mr. Ilsley's paper, Graham Bright remarked that mine equipment even if approved by the U. S. Bureau of Mines was not safe if not kept in proper condition. "At the end of several months approved equipment of the sliding fit type is no longer safe," Mr. Bright added as the result of his own observation. A bolted plate cover is permissible only so long as all bolts are in place and sufficiently tight to close all openings. Some system of inspection with proper authority given to those who make it, is needed and should apply to wiring and all electrical appurtenances. Something must be done to keep permissible equipment permissible.

Mr. Ilsley recommended that sliding fits be made of different metals and that the paths or ways be kept well lubricated. The Bureau, he added, had always insisted that permissible equipment was only safe when kept in condition, to which Mr. Bright replied, "Such equipment is not now kept safe; consequently there is only one solution to the problem, and that lies in daily inspections."

According to Henry Walker, deputy chief of the Mines Department of Great Britain, the same difficulty in keeping mining machines and other equipment in safe working order is experienced in that country where mine electricians are relied upon to inspect equipment.

Table III—Estimated Consumption of Timber in Bituminous Coal Mining

Year	Board Feet	Year	Board Feet
1923.....	2,021,950,000	1932.....	2,609,000,000
1924.....	2,062,760,000	1933.....	2,662,500,000
1925.....	2,114,700,000	1934.....	2,708,000,000
1926.....	2,175,000,000	1935.....	2,756,530,000
1927.....	2,226,000,000	1936.....	2,814,000,000
1928.....	2,330,000,000	1937.....	2,860,000,000
1929.....	2,415,000,000	1938.....	2,910,000,000
1930.....	2,485,700,000	1939.....	2,956,000,000
1931.....	2,547,000,000	1940.....	3,005,100,000

Fig. 4 shows the expected trend of bituminous coal production from 1923 to 1940 as based on data developed in Fig. 3. Using the unit of 3.71 board feet of timber per ton of bituminous coal mined, the growth in the use of timber during the same period in bituminous coal mining will be as shown in the right-hand graph of Fig. 4. It is expected, however, that the true average timber consumption per ton of coal produced will be slightly higher rather than lower than this weighted average. The values shown in the expected timber consumption curve of Fig. 4 are recorded in Table III.

The data from which the results shown were obtained are derived from thoroughly reliable sources and, so far as is known, are the most complete yet compiled.

Bolts are omitted in closed machines there just as here.

"An approved undercutting machine in permissible condition is a possible agent of ignition when cutter bits hit pyrite," said S. E. Reynolds. He related an instance in which a safe cutting machine working in a clay bed containing nodules of pyrite was believed to have caused an explosion. Because pyrite ignites at a lower temperature than coal dust, Mr. Ilsley classes its frictional ignition by the cutter bits of a mining machine as a possible source of ignition of coal dust or methane. George S. Rice remarked, however, that such a possibility is remote, considering the large number of cutting machines in use and the comparatively few explosions occurring. Mr. Allison was of the belief that frictional ignition of pyrite is possible and therefore should not be ignored. Mr. Reynolds held that cutter bits working on pyrite generate much heat and therefore might cause an explosion. As a corrective of this possibility Mr. Rice suggested that water be sprayed into the kerf while it is being cut.

Dr. R. V. Wheeler, director of the Government Experiment Station of the Mines Department of Great Britain, was one of the doubters, for he had tried experimentally, he said, to ignite methane by frictional sparks and had been unsuccessful under conditions similar to those existing in coal mines. A steel wheel was heavily weighted and made to revolve at 500 r.p.m. on a steel rail. Even the large stream of sparks thus resulting did not ignite a surrounding explosive mixture of methane with air so long as the sparks were permitted to travel freely and spend themselves in the atmosphere. Ignition, however, was obtained by setting an obstruction in the path of the sparks upon which they could impinge. These experiments led to the belief that frictional sparks must strike an obstruction and thus be enabled to have a prolonged period of contact with the gas if ignition is to be expected. A battery locomotive getting into motion on a sanded track is hardly a likely agent for the ignition of an explosive mixture of methane with air.

What Governor Pinchot's "Philanthropy" to the Anthracite Miners Means to the Public*

Wage Increase Far from Covered by Proposed Advance of 60c. per Ton—Labor Cost Now 170-180 per Cent Higher Than in 1913—Remedy to Consumer Lies in Recourse to Steam Sizes

BY E. W. PARKER

Director, Anthracite Bureau of Information
Philadelphia, Pa.

FROM the U. S. Coal Commission's preliminary report on anthracite the impression might easily be obtained that notwithstanding that business for the entire year of 1922 was "in the red," because of the losses due to the strike, it was a fairly prosperous year for the anthracite industry. In a statement showing the changes in margins from 1913 to 1923 (first quarter only) the average margins for each year are given for the years from 1913 to 1921 inclusive, while for 1922 a fair margin is given for the first quarter of the year, and a much larger margin is reported for the fourth quarter, and for the strike period covering the second and third quarters, it was simply marked "Suspension." It was, to say the least, disingenuous.

The commission evidently felt that it must respond to the public sentiment that exorbitant profits are exacted in the production and distribution of anthracite. Its tabulations of costs and profits showed that on the business done in 1921, the latest normal year, if the 60c. a ton which the Governor of Pennsylvania erroneously stated would be added to the cost by his present to the miners had been absorbed by the operators, 65 per cent of the tonnage would have been mined at a loss. However, as is well known, there are a few companies which, because of fortunate mining conditions, are highly prosperous. In order to prove this fact the commission accordingly published in detail the costs, realizations and profits of these companies from reports furnished with the understanding that they were to be held strictly confidential and which would not have been furnished had it been suspected that their confidential character would be violated.

REPORT THROWS LITTLE LIGHT ON WAGES

The report of the commission on the earnings of anthracite mine workers is one of the many academic products of that fact-finding agency, but it gives little information as to what are the actual earnings that the industry pays its employees. No attempt is made to carry one man or a number of men through the year. Consequently no allowance is made for labor turnover. A man employed during the year at three, four, five or a dozen different collieries appears as that many different men. As a result of this more than 64,000 miners appeared where only 36,500 were employed, and 76,000 miners' laborers apparently received the pay that was actually earned by 19,800. Comparison with other compilations of earnings that have been made cannot therefore be made. We may assume, how-

ever, that all employees who averaged 271 days or more were at the same job during the year, as that was the average days worked in the region in 1921. Every contract and consideration miner who worked this full time earned \$2,700 or over and 163 of them earned over \$4,000. All of the miners' laborers who worked as much as 271 days earned \$2,100, or over, but only one earned over \$3,000, and he earned between \$3,700 and \$3,800. Outside daymen who worked 271 days or more earned anywhere from \$1,200 to \$4,000, and inside daymen earned from \$1,300 up, and that is about as much as can be said on earnings.

10 PER CENT INCREASE RESULT OF ORGANIZATION

How the mine workers have benefited through the power of their organization—through the exercise of force in the settlement of wage agreements—had its latest exhibition in the increase of 10 per cent presented to them by the action of Governor Pinchot last September. When he forced this unexpected and totally unnecessary advance in wages to the miners, the Governor said that it would increase the labor cost 60c. a ton and he suggested with a charming naïveté that the operators might absorb 10c. of this amount and that the transportation companies and the retail dealers should absorb the other 50c., though through what sort of machinery this could legally be brought about he has not yet advised us. He was informed by the experts of the U. S. Coal Commission whom he had invited to advise him on the matter, that 60c. a ton would not cover the increased cost which would result from his proposed 10 per cent advance in wage rates, but that the cost would be 75c. or more per ton. He ignored their advice, however, and assumed responsibility for an incorrect statement which he has repeated upon several occasions since.

The Governor was, or should have been, familiar with some of the facts brought out by the report of the U. S. Coal Commission, and he should have known that if the anthracite operators had absorbed even the 60c. a ton that he erroneously stated would be added to the cost, 65 per cent of the anthracite tonnage would be produced at a loss.

The anthracite operators did not see things in the way the Governor would have had them do. They promptly added to their prices, "each to his kind," the cost which the Governor had by his action forced upon them, and firmly declined to enter into any agreement with him or among themselves to boycott any dealers who advanced their prices to their customers, although they were warned by the Governor that if they did not enter into this conspiracy he would attack the industry. And he has lost no opportunity to carry out this threat.

*Final installment of address entitled "A Few Comments on the Work and Reports of the U. S. Coal Commission," delivered at February meeting of American Institute of Mining and Metallurgical Engineers, coal and coke committee, held at New York City. The first part appeared in *Coal Age*, April 3, 1924.

The reaction that he got from adding to the already too high prices of domestic anthracite was not to his liking and he demanded that the operators rescue him from the pit which he had dug for himself and into which he had fallen, under the penalty of incurring his displeasure and the consequences thereof. He would use this "hard-boiled monopoly," as he calls it, to accomplish his own ends and having failed to obtain their consent to enter into an agreement, which Mr. Warriner, in a letter to the Governor, stated would offend the criminal laws of the United States, he has upon every occasion carried out his threat to attack the industry.

The Attorney-General of Pennsylvania, in an opinion to the Governor, said:

The operators can agree with each other to control prices for the benefit of the public without infringing the common law.

Legally, the operators might be in danger of prosecution under the Sherman law, if they agreed to hold prices below a maximum; but, practically, it is hard to find how they could be attacked unless the federal Department of Justice were hostile to action in favor of the public interest.

The Governor was perfectly willing to enter into an illegal alliance with the anthracite operators in order to serve his own purposes, and they (the operators) could have bought immunity (I use the term advisedly) from his attack had they been willing to run the risk of prosecution under the federal statutes. The Governor ran no such risk. Because they would not, they have become the objects of his vigorous vituperation and denunciation, culminating in the preparation by him and his Attorney-General of a bill which on Jan. 24 was introduced by Senator Borah into the Congress of the United States, and which calls for the regulation by bureaucratic Washington of one of the great industries of his state—a monopolistic industry, yes, but monopolistic only in the fact that it is confined entirely within the State of Pennsylvania; a monopoly created by Nature, not by men, and because of that condition brings revenue into the state amounting annually to approximately three-quarters of a billion dollars, of which about 70 per cent is expended for labor.

I do not know where the Governor got the idea that the anthracite industry is hard boiled in its "monopoly," unless it is because it is kept continually in hot water by the almost uninterrupted investigations of a more or less political character to which it is subjected. One is hardly terminated before another is begun. Here is a list of some of the investigations of the anthracite industry during the last ten years:

- 1914—Interstate Commerce Commission
- 1916—Gawthorp Commission
- 1917—Federal Trade Commission
- 1917—Department of Justice
- 1917-1919—Vardaman Committee, U. S. Senate
- 1918—Federal Trade Commission
- 1919—Governor Sproul
- 1919—U. S. Senate, Frelinghuysen
- 1920—U. S. Anthracite Commission
- 1920—U. S. Senate, Calder
- 1921—U. S. Senate, La Follette
- 1922-1923—U. S. Coal Commission
- 1923—Federal Trade Commission

The 10-per cent advance in wages obtained by the miners through the Pinchot settlement was something like superimposing Pelion on Ossa, as is evidenced by the fact that in 1913 the total commercial production of anthracite was a little over 71,000,000 gross tons, and the payroll was \$113,320,000; in 1921 the commercial production was 70,190,000 tons—a decrease of more than 800,000 tons from 1913—and the payroll increased to \$284,000,000. It is estimated that for 1924 the beneficent action of Governor Pinchot will, for the same tonnage as was produced in 1921, increase the payroll to approximately \$325,000,000.

The labor cost of producing a ton of anthracite in 1913 was \$1.595; in 1921 it was \$4.046. In 1913 the average wage for every man—from miner to laborer—amounted to \$644.80; in 1921 it was \$1,760.38.

The increase in labor cost in 1921 over 1913 was 154 per cent; the boost given by Governor Pinchot will make the increase from 170 to 180 per cent. The daily earnings per man increased 162 per cent from 1913 to 1921, and the annual earnings increased 176 per cent, the

larger percentage in the annual earnings being due to the fact that the men worked an average of 271 days in 1921, as against 257 days in 1913—and, by the way, 271 days is about as much as any wage earner works. The anthracite mine workers have averaged that number or better for the last six or seven years. The industry offers practically 100 per cent employment to its workers. No other basic industry does as well.

The advances to common labor—the lowest paid adult labor—have been at a much higher rate than to other classes of employment. In June, 1914, for instance, according to Research Report No. 47 of the National Industrial Conference Board, the average actual earnings for outside common labor were 18.3c. per hour; in 1921 they were 52.8c., an increase of 189 per cent, and this percentage increase in the pay of common labor in the anthracite region is to be compared with an increase of 117 per cent for common labor in the manufacturing industries and 138 per cent in the wages paid to common labor on the railroads. In the same time the cost of living had increased 64 per cent, so that the purchasing power of the anthracite mine workers' labor has shown a very substantial improvement.

WAGES IN ALL BUT COAL INDUSTRY LOWERED

The wage rates in effect in 1921, and up to September last, were fixed at the post-wartime peak of wages and living cost. Wage rates in nearly every other basic industry have since receded. The increase in the cost of living at the post-wartime peak was 105 per cent over 1914, and it has receded to 64 per cent. Not so anthracite wage scales. Mr. Lewis and his lieutenants have declared that there shall be no backward step, and the step taken in September, 1923, was certainly not to the rear.

The result of all of the foregoing is that the anthracite industry finds itself today in a position that may truly be stated as economically unsound. No one realizes this fact more than the anthracite operators. The

©Underwood & Underwood

Governor Gifford Pinchot

The Pennsylvania executive's settlement of the anthracite strike, granting the miners a 10 per cent wage increase, boosted the labor cost to nearly 180 per cent above the 1913 level.

prices of the domestic sizes are too high, and the prices of the small, or steam, sizes, as we have become accustomed to styling them, are too low. The spread between these grades of the same commodity, having practically the same heat-producing quality and differing only in size and in the methods required for their efficient utilization, is absurd. The high prices of the domestic sizes of anthracite unquestionably encourage the use of substitutes, such as bituminous coal, coke, oil and (particularly for coking purposes) gas, all of which, strange to say, this "hard-boiled monopoly" is powerless to prevent.

It is impossible, however, in the face of such high producing costs, to effect any substantial reduction in the prices of the domestic sizes unless a more remunerative market can be obtained for the smaller sizes, which are now by far the larger part sold in competition with bituminous coal. There is no immediate prospect of obtaining any reduction in producing costs.

The anthracite operators cannot depend for long upon what S. D. Warriner has designated as the anthracite-consuming habit, and which, as he says, is the chief asset of the anthracite industry, but it is realized that consumers of anthracite—or at least the large majority of them, who are the people of moderate means—will not continue to indulge that habit when what they have always considered as a commodity, or certainly a comfort, is elevated to a superluxury class of fuel.

REMEDY IS ELEVATION OF SMALL ANTHRACITE

The remedy for the present situation is in elevating the smaller sizes of anthracite from their present degraded position of competing with bituminous coal for power raising—a use for which they are admittedly not so well adapted as is good bituminous coal—and placing them with their larger brothers in the domestic trade. It is entirely practicable; and it is not only practicable, it is economical, as has been demonstrated by elaborate tests carried on not only by fuel engineers employed by the anthracite operators but in university engineering departments, particularly Yale and the University of Pennsylvania.

However, there are now on the market appliances in which the small sizes of anthracite can be used with entirely satisfactory results for domestic heating. Among these may be mentioned the Spencer, the Molby and the Newport heaters, all of which burn buckwheat coal with automatic feed, and, if desired, with thermostatic control, also automatic, and with natural draft. A new device appropriately styled "The Electric Furnace Man," recently put on the market, uses rice and barley or even smaller sizes, automatically feeds the coal and removes the ashes, and can be operated under thermostatic control. It is operated with a blower attachment.

There are other devices which may be applied to the ordinary heating apparatus, which consist chiefly of using a forced draft either with or without automatic regulation by thermostat and with entirely satisfactory results. The people of Harrisburg, Pa., who are not responsible for the conduct of the occupant of the Governor's mansion, have for a number of years been using small sizes of anthracite, recovered from the bed of the Susquehanna River, in ordinary furnaces with a simple blower attachment. I am informed that there are more than 3,000 installations of this kind in Harrisburg and vicinity.

The steam sizes can be used with economy not only in the price of the coal but in the use of the fuel itself

by mixing these sizes with the customary fuels. For banking the fires at night the small sizes are much to be preferred to the ordinary fuel, as they make a more compact covering to the fuel bed and materially quicken the regeneration of the fire in the morning. The mixing of these fuels should never be done in the coal bin. Separate bins should be maintained for the small sizes and the regular fuel. One of the chief objections, it has been found, to the use of these small sizes in this way has been the necessity for an extra bin in the cellar, and in small houses the building of another bin sometimes proves a real inconvenience.

PREJUDICE AGAINST SMALL SIZES UNFOUNDED

There has existed an unreasonable prejudice against the use of the steam sizes for domestic purposes, one reason probably being the fact that they are sold at prices much below the domestic sizes, and it is considered, therefore, that they must necessarily be of an inferior quality. Where they have been given an intelligent trial, however, they have proved their value, and it is gratifying to state that the prejudice is gradually disappearing. The use of the steam sizes will be found more satisfactory than the use of either retort, beehive or gas-house coke. These are safe and smokeless fuels, but they are porous, consequently bulky, occupy a much larger space than the same quantity of anthracite, are difficult to handle, and unless great care is taken in the draft control they burn out much more rapidly than does anthracite. There is no other solid fuel that will maintain the uniform temperature for the length of time that anthracite will.

The anthracite operators are now taking active steps to educate the public in the use of these small sizes, and in co-operation with the manufacturers of the equipment I have mentioned and of others have established "Coal Economy Shows" in several cities where, in addition to the heating appliances shown, there are educational exhibits worthy of attention and moving-picture entertainments are given in which the story of anthracite from the original forest growth to the finished product loaded on the cars for market, is interestingly told.

Testing Coarse-Size Coal

A float-and-sink method and apparatus for testing coarse-size coal, developed by the U. S. Bureau of Mines in co-operation with the College of Mines, University of Washington, at the Northwest Experiment Station of the Bureau, is described in Serial 2570.

Two separate methods and apparatus have been developed for the float-and-sink testing of coal, one for coarse sizes and the other for use with the fine sizes of coal. The practical division between coarse and fine coal for such tests is about 20-mesh. The apparatus and methods described are confined to sizes coarser than 20-mesh for any except rough work.

A float-and-sink test of a coal sample is a means of separating in a heavy liquid the free particles of coal from associated impurities according to differences in their respective specific gravities. When the sample is placed in the liquid, the particles of specific gravity lower than that of the liquid float; those of higher specific gravity sink. This method of separating coal from its impurities is so positive and exact that it is much to be regretted that the cost of suitable solutions now prohibits its use in actual coal beneficiation.

Track, Diamond Mine, Imperial Coal Co.

Making the Application of Electricity Safe Against Hazards to Person and Property

Every 110-Volt Current with Proper Contact May Cause Death and Gas May Be Ignited by 2-Volt 1-Amp. Electric Bulb—Operation of Wireless Mines May Be Not Only Safe But Advantageous

BY L. C. ILSLEY

Electrical Engineer, U. S. Bureau of Mines

BACK of every safety program stands the industry itself with its precedents, prejudices and traditions. Coal mining, being an old established industry, naturally had many fixed traditions long before electricity and electrical equipment, comparatively new forces, made their appearance.

The electrical engineer, in spite of these traditions, thrust himself and his equipment into this field and insisted, often without invitation, upon taking a prominent part in the future development of coal mines. Therefore, it naturally follows that certain readjustments must be made from time to time to take care of the new problems introduced by electricity. Further, these adjustments will never be permanently or satisfactorily made until the electrical engineer, the mining engineer and the safety engineer thoroughly understand each other's problems and jointly work out a practical solution based upon the needs of industry and the limitations of electrical design.

The safety movement in coal mining had made considerable advance before the advent of electricity. As early as 1869 we find a safety code, covering one county in the anthracite field of Pennsylvania, and by 1888 there were at least 12 states having safety regulations for bituminous coal mines. These early safety codes, made previous to the introduction of electricity, naturally had no reference to it or to the installation and operation of electrical apparatus, and in some states, even after successive revisions of the safety code, there are still no adequate rules covering electrical equipment. For instance, a chief mine inspector or his deputy, is not, as a rule, legally required to have a

knowledge of electricity or an understanding of safety measures concerning the installation of electrical equipment.

The growth of the coal industry in the United States has been remarkable. Yearly tonnage statistics, published by the Geological Survey for both anthracite and bituminous mines since 1822, not only show the rapid growth of this industry, but also indicate the part

Electric Lights at the Mine Face

Taking a leaf from the practice of other industries which have long ago learned that adequate lighting pays, the mines are now beginning to improve the illumination of their underground workings. Here is an application of electricity which will reduce mining hazards far more than the use of electricity for machinery has increased them.

*Abstract of paper entitled "The Present Trend of Electrical Safety in Coal Mines," presented before American Institute of Electrical Engineers, Birmingham, Ala., April, 1924.

New Drives Replace Old

Where the equipment to be operated is still in good condition it often has been found advisable and economical to replace the old drive with an electric motor. Such changes are usually difficult to make because of the many special conditions to be met.

which electricity has played in bringing the total output of coal to the present figures.

Beginning with 58,583 tons in 1822, there is almost an unbroken yearly increase until we reach the maximum of 678,211,904 tons in 1918. An increase of 10,000 per cent in a little less than 100 years.

The increase in bituminous production during each decade for the last 50 years is shown in Table I.

Table I—Increase in U. S. Bituminous Coal Production

Decades	Average Yearly Production—Short Tons	Decades	Average Yearly Production—Short Tons
1871 to 1881	32,600,000	1901 to 1911	323,000,000
1881 to 1891	82,800,000	1911 to 1921	486,800,000
1891 to 1901	148,500,000		

The increase in coal output during the last 25 years has been augmented by the introduction of electrical equipment which, owing to both economy of operation and flexibility, has found a real place in the industry. It was impossible to find suitable statistics showing the growth in the use of electrical equipment in coal mines. However, Table II has been compiled from such data as could be found. This table gives an indication of increases during the last two decades.

The first electric hazard is shock. No person can be sure that he will not be killed, even from a 110-volt circuit, if his body makes such contact with it that the maximum current passes through his body. As the voltage is increased to 250 volts, 500 volts, or 2,300 volts, the danger from contact with the electric circuit is increased. Alternating current of the same nominal voltage is possibly more dangerous than direct current. Experience has taught us that both will cause death, and if the fatalities from this source are to be kept low, certain precautions in the guarding of circuits must be observed.

A second hazard is in the use of explosives in conjunction with electric current. It seems unnecessary to advise against the placing of any electric wiring in a powder magazine. If a flash or arc from an electric circuit comes in contact with black powder, an explosion results. Therefore, all boxes and cars should be so constructed that current from the trolley or from the rail cannot possibly pass through the sides of boxes,

Table II—Increase in Use of Electrical Equipment in Bituminous Mines

Year	No. of Motors	Total Hp. of Motors
1902	1,322	65,927
1909	10,557	402,090
1919	42,230	1,578,474

Old and Modern Power Transmission Lines Keep Company at Coal-Mining Properties

The rapid strides made in the electrification of the mines have brought about interesting associations of old and new equipment. Original power distributing lines look much out of place when compared with the latest installations. At many mines the old must stand with the new because of the urgent demands to electrify and mechanize both obsolete and modern equipment.

Switchroom Where Circuits Are Controlled and Supervised by Definitely Appointed Workmen

To make sure that no switch may be wrongly closed or left open each enclosing cabinet is marked with wording indicating its circuit. Many such switches now used are arranged so that they may be locked open when men are working on the lines.

and so that it is impossible for the metal powder cans to form a path for the electric current.

Electric current is very useful for electric shotfiring, and undoubtedly safer than fuse and squib firing, but great care must be taken lest the shot is prematurely fired by an accidental current passing through the electric detonator. Detonators and explosives should always be kept apart until used, also great care should be taken to keep shotfiring from other electric wires, and finally, detonator leads should be prevented from contact with electrical circuits or apparatus, as less than 1 ampere of electric current will fire an electric detonator.

A third source of danger is the ignition of gas from electric flashes or heated wires. It takes but a tiny current of 250 volts to ignite gas. It has been found that the current required to operate the motor of an electric drill under no load is sufficient to ignite gas. Again, the incandescent filament of a 2-volt, 1-amp. bulb will ignite gas very readily.

A fourth hazard is the ignition of coal dust by electric arcs or flashes. Some bad coal mine disasters have undoubtedly been caused in this way. Tests made by W. Thornton in England and by H. H. Clark of the U. S. Bureau of Mines proved that ignition of clouds of coal dust by electric flashes could readily take place. The greatest danger occurs, in case of a wreck of a trip of cars, which wreck may tear down or damage an electric circuit and at the same time stir up a heavy dust cloud.

A fifth danger is from fires of electric origin. These may be caused by short-circuited cables, by grounded feeder or trolley circuits, by grounded lighting circuits, by overheated motors or starting devices, by heating from incandescent lamps improperly placed with reference to flammable material, or by short-circuited transformers or defective switches.

The operator should be given credit for what is perhaps the most forward step in regard to electrical safety in coal mines, namely, the introduction of the "wireless mine." The possible hazards of extensive electric wiring in gaseous and dusty coal mines are so great that at least two large coal mine operators, one in West Virginia and one in New Mexico, are laying their plans for an electrically operated mine without permanent electric wiring. Why does one install wires? The answer is, for transmitting energy from the power plant to the place where energy is used. If the power

plant could be located at the coal face, no permanent wires would be needed. Then, if wires are potential danger, let us do away with them and place the power plant on wheels, taking it to the point where energy is needed. Any piece of work can be done better by energy obtained from a constant source of potential, such as would be delivered by a storage battery, provided the battery is large enough for the job. Having no wires to install, no tracks to bond, no voltage drop over long feed lines to consider, one can afford to invest heavily in a portable power plant. When the advantages from a safety standpoint are considered, the venture is certainly worth a thorough tryout.

Imagine the security the operator of a "firey" mine could feel at the end of the shift, knowing that there are no feeder or trolley circuits to become grounded over night, no switches to be left closed when they should have been left open, that when the mine stopped its work all its electrical equipment came out of the mine or at least was brought to a fresh air base to remain there until the next day's work begins.

The wireless mine has the advantage of having the equipment that carries the live electric current always under close supervision and also in that such equipment will only be in the gaseous portion of the mine during the working shift, whereas in a wired mine, the wires are there all the time, a large portion of which time they may be without close supervision.

The operator is demanding safe electrical equipment. One manufacturer of approved equipment reports 300 per cent increase in sales during 1923 as compared with the sales of any previous year. The operator is not only demanding more approved equipment, but is asking for new lines of approved equipment such as hoists, air compressors, pumps, and loading machines.

In the future, as far as is feasible, it is understood that manufacturers intend to carry only two lines of equipment, the open type for non-gaseous mines, and the permissible type approved by the U. S. Bureau of Mines for use in gaseous and dusty mines, thus eliminating the so-called "flame-proof" type, built along the same lines but not having the careful factory inspection or the additional inspection and test given by the Bureau to permissible equipment.

Drive with Exposed Commutator Is Unsafe

Most of the first electric drives were by means of direct-current motors. Unless carefully protected and housed they may, in the class of service shown in the illustration, give serious trouble. Note the unprotected terminals which might cause a bad fire if a piece of metal were to fall on them. The open motor with exposed commutator is liable to flash and thus fire the oil-soaked coal dust.

A Few Changes in Usual House Plans Afford Miner Comfort

Enclosed Porch and Entry Protect the Interior, and Notably the Dressing Room, from Drafts—Clothes Closets, Cellar and Bath Add Convenience

BY PHILIP A. ARNOLD
Shawmut Mining Co., St. Marys, Pa.

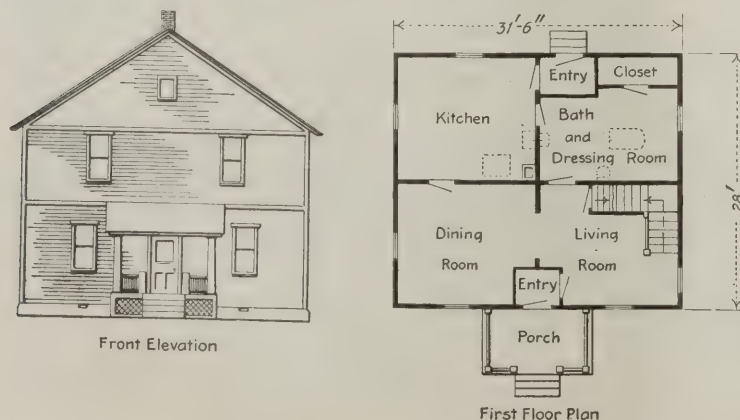

ENDEAVORING to view the miner's house from the point of view of the man who has to live in it, and not so much from other considerations, I have prepared some house designs in which comfort and inexpensiveness have been the paramount idea and not exterior decoration. Briefly stated, my general plan has been to adopt a square or rectangular form of house as being the most economical type to build. There are no wings or ells, which materially increase the cost of erection and involve expense for repairs and maintenance, par-

Four-Room House for Man and Wife

House is almost square thus saving on cost of construction. Note how the dressing room is protected from drafts by both doors of the enclosed porch and the kitchen door.

ticularly in the roof construction. I am giving, here, three plans of eight-, six- and four-room houses designed for practical low-cost building, as well as desirability from the tenant's point of view. The dimensions given on these plans are only suggestive and can be changed to suit local conditions. A foundation of concrete, tile or brick is absolutely necessary, in most coal regions, if the house is to be kept warm and comfortable. Observation shows that a too common practice has been to set these miners' houses on posts, elevating them a foot or more above the ground and leaving it to the option of the tenant to inclose this space if he cares to do so. The

House Has Six Rooms, Two of Which Are Bedrooms

In this house are two clothes closets. The same "air locks" protect the interior from rushes of cold air through open door ways. The bathroom is a little smaller than some of the other rooms but large as a bathroom should be where it has to be used for removal of dirty clothes.

result is that often old boards, barrel staves or anything else that may come to hand have been used for the purpose. While this is better than nothing for keeping out the snow and, to some extent, the wind it is needless to say that it makes the house extremely unsightly.

EVERY HOUSE SHOULD HAVE A CELLAR

For general utility, every house should have a cellar provided with an outside entrance. It may not be necessary to excavate the entire space within the foundation of the building; but the cellar should be large enough to afford room for keeping tools, vegetables and a small supply of coal. It is far better to have the coal under cover than to have it piled against the side of the house or at the back, where it is exposed to the weather which tends to disintegrate it and render it unfit for use.

Outside coal-houses and wash-houses do not add to the comfort of the miner's home, or the attractiveness of the property and the town. These can all be avoided when the house is properly designed and a small cellar provided. Make the house a home and afford ample room for a small yard and garden surrounding the building. With a little encouragement, most of the miners' families occupying these houses can be readily induced to plant trees, bushes, vines and a garden that will make the place attractive and give it a homelike appearance.

The main feature in these houses is a bath and dressing room opening out of the kitchen. This is a prime necessity in most miners' homes. With a bath on the first floor there will be no tracking through the house when the miner comes home from his work. The bath or washroom should be so arranged that the man can wash and dress with ease and comfort, on his return from work. Place should be provided where he can

Two-Story House

The stairway cuts into the living room but the ground plan is larger than with the four-room house making all the rooms of adequate size.

hang his working clothes to dry in readiness for the following day.

Many may prefer a washroom in an outside shed, because when that is provided the dirt and coal dust incident to mining is not brought into the house. In any event, it would seem that, with an outlay that is not prohibitive, each house could be provided with running water that would relieve the occupants from the steady grind of carrying water from the nearest street hydrant. In mining towns this is not an infrequent living condition.

One feature that is worthy of mention is the provision made in two of the plans, here presented, for an inclosed entry. This is always desirable and will be

appreciated by most tenants where the front door of the house opens directly into the living room. A third plan shows an inclosed entry built out on the porch, which is often done in case the house is small or the size of the rooms limited. In the eight-room house, it will be observed that a space for a stairway leading to the attic above the second floor has been provided. In this plan and also in the six-room house some closet room is also arranged. One never realizes how useful closets are until one lives in a house built without them.

It is not to be supposed that these plans will meet the needs and requirements in all cases. Everyone has his likes and dislikes and what is suitable for one family may not meet the needs of another.

The Miner's Torch

Things Are Not Always as They Seem

A MAJORITY of the companies that own and operate coal mines own and operate commissaries in connection therewith; the average coal-mine manager and likewise the average coal-mine superintendent although not responsible for the operation of the commissary at his operation has been in such close contact with the institution all through his mining career that he assumes as a matter of course that he could add the management of a commissary to his other duties without any trouble whatsoever. Fortunately the average manager and the average superintendent is not called upon to take over the actual management of a commissary, so no harm comes to the superintendent or his company from the assumption.

Some years ago (at the time I considered myself an average mine manager) I was offered a lease on a complete coal-mining property, and included in the deal was a well-stocked commissary. By the terms of my lease I was required to take over the commissary stock and pay the inventory price for same. Before agreeing to the purchase of the merchandise I decided to have the stock passed upon by men who were posted in the various lines and only after discussing the matter with them did I sign the papers that put me in possession. The stock judged by inventory value was about equally divided between groceries, dry goods and shoes.

The man who passed on the shoes for me was an employee of a shoe jobbing house and he reported that the stock was in good condition and there was a fair assortment of sizes, except that most of the larger sizes were missing. There was the joker but he didn't know it and I didn't know it.

I owned that stock of goods exactly one year and in that length of time the commissary manager that I employed was only able to dispose of two or three pairs of the shoes that I had acquired in the original purchase. All of the miners in that camp had large feet and they had purchased all of the shoes from the stock that were salable in that community before my ownership. Do miners everywhere have large feet? Not having been everywhere I hesitate to answer.

The commissary manager who had originally purchased the stock had had no previous experience in mining camps and in buying the shoes he simply

ordered a complete assortment of sizes. That was before the days of questionnaires; I suppose the procedure today would be to send out a blank to each male citizen and get full details relative to sizes and preferences before stocking up the commissary shelves.

Where did I fall down as a commissary manager?

First: I showed bad judgment in my choice of appraisers.

Second: I showed bad judgment in my choice of commissary manager. A little advertising in near-by communities would have allowed me to realize on the shoes that we could not move, but I did not realize that until my successor's commissary manager turned the trick.

There was probably a third, fourth and fifth but there is a limit to the information one can acquire in one year.

HYDROGEN AS A CAUSE OF EXPLOSION IN COAL DUST.—T. G. Fear, general superintendent, Inland Collieries Co., in discussing J. W. Paul's paper on "The Explosion Hazard Investigations of the U. S. Bureau of Mines," at a recent safety conference said he had been disposed to believe that the hydrogen content of the coal affected its degree of explosibility, for in the Southern states most of the explosions occur in mines working coals containing much hydrogen. This suggestion met with no support, Mr. Paul stating that the higher the ratio of volatile to combustible matter the greater the explosibility of the dust. For Pittsburgh coal the ratio is 0.4 but for coals further east the ratio is less. Mr. Fear said that coals high in hydrogen contain more waxey material and it is this material which, when in the form of dust, tends readily to explode. Mr. Allison, of the U. S. Bureau of Mines, said that the ratio of volatile to combustible matter was a more important indication than the hydrogen content.

BULLETIN 84 OF THE STATE TOPOGRAPHIC and Geologic Survey, on "Coal Reserves in Clarion County," by James D. Sisler, has been published by the Pennsylvania Department of Forests and Waters. According to the bulletin, 1,262,000,000 tons are recoverable. There are twelve coal beds in the county, the bulletin shows, four of which are now being mined for shipping coal, five others being mined for local fuel and the remainder having little commercial importance at present. The Lower Kittanning coal is the most persistent and largest producing bed in Clarion County. The Clarion Lower coal contains the largest quantity of recoverable coal but is variable in thickness everywhere except in the southwestern part of the county.

News Of the Industry

Utah Adopts "100-per Cent" Safety Code Following Castlegate Blast

Requires Permissible Explosives, Electric Cap Lamps, Careful Rock Dusting, Thorough Wetting of Working Faces and All Dusty Places and Most Careful Reporting and Handling of Gas Pockets

Utah is going to make its coal mines as safe as men know how to make them. A new and drastic safety code and a fresh determination to stop mine accidents have risen out of the public shock caused by the March 8 explosion at Castlegate No. 2 mine of the Utah Fuel Co. in which 171 men were killed. The new code, adopted by the State Industrial Commission after it had been written in a conference between state mine inspectors and operating men, requires the use of permissible explosives only, the use of nothing but approved electric cap lamps, calls for all shots to be fired electrically when men are out of the mines, and lays down some strict requirements for wetting every mine. It is said to be the most rigid safety mining code in America.

Investigators of the Castlegate explosion finally concluded that without doubt the blast was started by the attempt of a fireboss to relight his flame safety lamp. A pocket of gas was ignited and coal dust throughout the mine that was improperly sprinkled did the rest. Laxity in reporting gas accumulations and failure to sprinkle abandoned workings were condemned in the report of B. W. Dyer, chief mine inspector; John Crawford, state coal-mine inspector, and H. E. Munn, coal-mine engineer for the Industrial Commission.

Recommendations Now in Effect

This report was considered in a long conference between the three state mining men and a committee representing the operating interests of the state. It was approved almost in entirety and the new code of safety came out of the conference. Not only is the Castlegate report accepted as correct by the Utah Fuel Co. but Frank N. Cameron, vice-president of the company, said most of the recommendations of the investigators have already been put into effect by that company.

The company men who helped frame the new safety code were L. F. Rains, Columbia Steel Corporation; A. C. Watts, William Littlejohn, Utah Fuel Co.; R. M. Magraw, J. B. Forrester, U. S. Fuel Co.; P. H. Burnell, Lion Coal Co.; Charles Ledger, Royal Coal Co.; J. R. Loaf, Independent Coal & Coke Co.; Thomas R. Stockett, Spring Canyon Coal Co.; William Money, Kin-

HERE'S THE GIST OF IT

Utah's new "100-per cent" safety code, more drastic than that of any other state in many particulars, requires:

- 1—Permissible explosives only.
- 2—Shotfiring by electricity.
- 3—Approved electric head lamps.
- 4—Rock dusting in all mines.
- 5—Use of water for cutting and loading machines to reduce dust.
- 6—Sprinkling at every face.
- 7—Daily reports on sprinkling.
- 8—Sprinkling to be done by men employed for no other duty.
- 9—Shutdowns during removal of gas accumulations.
- 10—Cleaning up of all abandoned workings.

ney Coal Co.; B. P. Manley, Carbon Fuel Co.; R. W. Van Derck, American Fuel Co.; George A. Schultz, Liberty Fuel Co.; Robert Howard, Peerless Coal Co.; B. Newren, Scofield Coal Co., Union Pacific mine; A. Shaw, Mutual Coal Co.; H. E. Lewis, Standard Coal Co.; H. Tomlinson, MacLean Coal Co.; J. H. Roberts, Weber Coal Co. and Grass Creek Fuel Co.; William Littlejohn, Blue Seal Coal Co.

The safety code, by which Utah leads all other states in the requirements laid down in the first seven sections, follows:

"(1) Permissible Explosives.—Only 'permissible explosives' shall be used for blasting coal in any mine, and the amount of such explosive used in any one hole shall not exceed the permissible limit of 1½ lb. A permissible explosive shall be considered as one which has been classed as permissible by the U. S. Bureau of Mines, and then only used in such quantities and under such conditions as have been approved by the U. S. Bureau of Mines.

"(2) Shotfiring.—In all coal mines in Utah in which three or more men are employed on any one shift, all shots shall be fired electrically by authorized shotfirers, when all men, except the shotfirers, are out of the mine.

"(3) Lighting.—All men entering coal mines in Utah in which more than five men are employed on any one shift shall be equipped with electric lamps approved by the U. S. Bureau of Mines and no flame lamps shall be permitted in the mine, except for testing purposes. All lamps used for testing purposes shall bear the approval of the U. S. Bureau of Mines and shall be magnetically locked and the igniters shall be maintained in a serviceable condition. Mines employing five men or less on any one shift may be required to comply with the above regulation at the discretion of the Industrial Commission of Utah.

"(4) Rock Dusting.—All main entries and slopes of coal mines in Utah shall be rock dusted from the mine opening into a point designated by the state mine inspector. Intake air courses shall be rock dusted at least into the most distant points where freezing takes place in the coldest weather. Whenever, by analysis, the rock dust material in any part of a mine so treated shows a total incombustible content lower than that determined as necessary to render the coal dust inert, the section in question shall be fenced off, or the mine closed until sufficient inert material has been added to allow of safe operation.

To Prevent Spread of Blasts

"(5) At every opening from each working panel or level connecting to any other level or panel, entry or slope, there shall be installed rock-dust barriers so placed that an explosion originating in that level or panel cannot extend to other parts of the mine. These rock-dust barriers shall be of a type which has been tested and approved by the U. S. Bureau of Mines, and shall be correctly installed.

"(6) Water on Mining Machines and Mechanical Loaders.—Coal-cutting machines and mechanical loading machines shall not be operated in coal mines in Utah unless equipped with a supply of water applied in a manner to wet down and prevent the raising of fine coal dust into suspension in the air.

"(7) Sprinkling.—Every owner, agent, manager or lessee of coal mines within the State of Utah shall provide and maintain water lines in all working places of sufficient size and pressure to furnish water in sufficient quantities for sprinkling purposes to wet down all coal dust that may arise and accumulate in and around the working face. And each worker shall be kept supplied with a sufficient quantity of

Rescue Team at Castlegate

But the word "rescue" is a misnomer, for all the men in the mine perished.

water hose to enable all parts of the face region to be thoroughly sprinkled, this to be used by the workers in each working place.

"(8) Men employed for sprinkling shall make a signed daily report, in a book kept for that purpose, of the sprinkling work done, condition of working places, pipe lines, and any difficulty arising from the lack of pressure, pipeline shortage, breakage, lack of hose, etc., this report to be countersigned by the mine foreman.

"(9) Men employed for sprinkling shall not be used on work other than sprinkling without first having the permission of the superintendent for such transfer, it being understood that in case of such a transfer the vacancy shall be filled by a man qualified to do that work.

"(10) Ventilation.—Moving of gas (methane) accumulations while the shift is in the mine is absolutely prohibited even when all miners are on a closed-light basis, and the entry in which the accumulated gas is found, together with all workings on the return side of the same split in which the accumulated gas is found, shall be closed down until the gas is removed by approved methods of ventilation.

"(11) General Orderliness.—Before the track is pulled out of the air courses, abandoned rooms and other places, all coal and coal dust must be cleaned up and loaded out. This, however, does not apply to rock and bone gobs in rooms and other places that have been adequately rock dusted.

"That the orders herein made (except order No. 4, relating to rock dusting, and order No. 6, relating to water on mining machines and mechanical

loaders, these orders to be effective as provided hereafter) shall and they are hereby made effective on and after July 1, 1924; provided that in the case of order No. 4, relating to rock dusting, additional time may be granted by the Industrial Commission to any operator who, by written application, applies to the commission for an extension of time, provided in the opinion of the chief mine inspector said operator has exercised due diligence in an effort to comply with said order; said additional time, however, to not extend beyond Sept. 30, 1924; and be it further provided that in case of order No. 6, same shall be effective on and after June 1, 1924; and,

"That all orders and parts of orders contained in the general coal-mine safety orders of the Industrial Commission effective Sept. 1, 1920, which are in conflict with the orders herein made are hereby rescinded, vacated and set aside."

F. L. Burns Named President Of Burns Coal Co.

The resignation of Michael F. Burns as president of Burns Bros., New York City, was accepted at a meeting of the directors April 8, and F. L. Burns, his son, was elected president of the company. Michael F. Burns was elected chairman of the newly created advisory committee, the other members of which have not been chosen.

The directors declared the regular quarterly dividends of \$2.50 on the Class A stock and 50c. on the Class B stock, both payable May 15 to stockholders of record May 1.

West Kentucky Parley Off; Miners Refuse Wage Cut

Special Dispatch to Coal Age

Louisville, Ky., April 14.—Negotiations were broken off between the Western Kentucky Coal Operators Association and District No. 23, United Mine Workers, this morning when on reopening the conference on a new wage agreement, the miners issued an ultimatum to the effect that they would accept nothing other than the so-called Jacksonville agreement, or a three-year contract at the 1919 scale as adopted by the Central Competitive Field, of which western Kentucky is not a part. The operators wanted a return to the 1917 scale, due to non-union competition and disadvantage in freight rates in competing with the Central Competitive Field. The ultimatum stated that the miners could not accept any reduction, not having the authority to do so. This is taken to mean that John L. Lewis, International president, is responsible for the refusal, as the men had previously shown a disposition to accept a reduction agreement. The operators issued a statement and the conference was abandoned, the men returning to their homes.

It is predicted that some of the mines will soon open on a non-union basis, while others will make no attempt to operate for the time being. The original expiration date of the contract was April 1, but this was extended to April 15, in order to give the miners time for conference with Lewis. The operators will now offer the reduced scale, and operate if enough miners report.

President Lewis at Indianapolis definitely refused, several days ago, to sanction any sort of wage reduction in western Kentucky. He is reported to have hurled some strong language at District President Jackson and the committee of union men from Kentucky. Thus it was left for Jackson to go back and do the best he could. The impression got abroad that if Jackson agreed to the 25 per cent cut the operators demanded, Lewis would promptly make an example of him in an effort to hold the other wobbling outlying districts in line.

These negotiations cover only the east half of the western Kentucky field, comprising Muhlenberg County mainly. There is a union contract called the Madisonville agreement outstanding another year in the western half of the field, but few indeed are the companies operating under it, for there is little union strength left there.

Freeport Vein Operators Sign

A wage agreement has been signed by the wage scale committee of district No. 5, United Mine Workers, and officers of the Freeport Thick Vein Steam Coal Operators' Association, P. T. Fagan, president of the district mine workers, announces. The pact affects about 10,000 mine workers in the Pittsburgh district.

The agreement is based on the Jacksonville settlement and will run for three years.

Bath and Change House at Castlegate

In this house, 100 ft. from the main entrance of the mine, every window was broken. The drift mouth itself was demolished by the explosion and caved in.

Comes into control of vast industrial enterprises through the death of his father.

Two Lives Lost in Flood of Four Glen Alden Mines

Four mines of the Glen Alden Coal Co., near Scranton, Pa., were flooded and three others seriously threatened April 7 by the swollen waters of the Lackawanna River, which broke through on the westerly side, below the National colliery, in Taylor. Company officials and employees labored tirelessly in an effort to halt the flood. Two miners employed in the Sloan mine lost their lives. The bottom workings of the Bellevue, Dodge, Hyde Park and Sloan mines were inundated and the Taylor, Pine and Archbald workings were menaced.

After thirty-six hours of work by nearly 800 miners, who dropped ten steel cars, 100 tons of steel rails, 50 tons of baled hay and several thousand bags of sand into the opening, the course of the river was diverted from the opening. It will take several weeks to clear the workings of water.

Senate to Pass Johnson Bill

Passage of the Johnson immigration bill by the U. S. Senate by an overwhelming majority is indicated as *Coal Age* goes to press, an attempt to amend its provisions to continue the "gentlemen's agreement" under which the Japanese Government is pledged to refuse permission to coolie laborers to emigrate to the United States having been defeated April 14 by a vote of 76 to 2. The House passed the bill April 12 by a vote of 326 to 71.

As the Johnson bill goes to the Senate, it provides that immigration in the future shall be based upon the census of 1910 instead of 1890.

It permits immigration from each nationalistic group to the amount of 2 per cent. of the number of such nationals resident in the United States as recorded in the census of 1910. It is estimated that under its provisions immigration would approximate 161,990 a year, as compared with an average of 357,801, under the present law, which fixes immigration on a 3 per cent quota.

Stinnes, Industrial Czar Of Germany, Dies

Hugo Stinnes, industrial and financial leader of Germany and one of the wealthiest men in Europe, died in Berlin April 10. He had been operated on twice for gallstones, after which his condition was complicated by peritonitis and pneumonia. It is believed that his fatal illness was brought on by the Ruhr occupation, chagrin, worry and overwork.

Hugo Stinnes was born in Mullheim in 1870, of Jewish parentage and belonged to a wealthy family that long had been prominent in commerce. He received a common school education in his native town and then worked as a miner and in a business office to gain practical experience. He started business for himself as a coal dealer, bought several coal mines and then branched into transportation, buying river steamers and barges and ocean-going vessels. He became a director in many corporations in Germany and Luxemburg, especially those engaged in supplying electric power and lighting.

Stinnes was the foremost profiteer of the World War; was intrusted by Ludendorff with the industrial looting of Belgium and had charge of the production of munitions. He bought many newspapers in Germany which he used for the promotion of his profiteering schemes. He was elected a member of the Reichstag in June, 1920, as a member of the German People's party, and later sought to organize a supertrust to control every industrial and commercial enterprise in his country.

Governor Fields Intervenes To End Mine Warfare

In an effort to arbitrate the differences which brought about warfare in the mining camp on Straight Creek, Governor Fields, of Kentucky, held conferences April 12 with R. R. Atkins, general manager of the Liberty Coal & Coke Co.'s mine at Straight Creek, and William Turnblazer, president of District No. 19, United Mine Workers; Sanford Snyder, International union representative, and two miners from Pineville, representing the local union involved. The Governor held separate interviews with the representatives of both sides of the controversy, but no announcement has been made as we go to press.

All last week the armed conflict between state troops and mountain snipers kept up around the plant of the Liberty Coal & Coke Co. on Straight Creek, near Pineville, Ky. A good many shots were fired from various points around the hills toward the company's property under protection of the troops, but no hits were reported. The mountaineer dead shots among the union miners who refused to work at the 1917 scale and were consequently evicted, hit nobody except the three men shot down April 3.

It is supposed that numerous unemployed union miners from other fields have come in to help in this struggle to regain the union's foothold at the Liberty property, which is in the center of a hotbed of unionism in and about Pineville.

A. J. Cook Elected Secretary Of British Miners Union

A. J. Cook, leader of the South Wales coal miners, has been elected secretary of the Miners' Federation of Great Britain, succeeding Frank Hodges, who resigned the post upon his appointment as Civil Lord of the Admiralty in the labor government. When interviewed by the Associated Press on his appointment, Cook, who is an avowed extremist and devoted to the Marxian theories, said he interpreted the miners' choice as a desire for an aggressive policy.

"I am in favor of a real live national and international miners' organization," he said, "and am convinced that the miners cannot retain even their present bad conditions without it. I am still a Red with all that means, and I will not rest satisfied until private enterprise in the mining industry is abolished."

Upper Kanawha Wage Parley Broken Off

Negotiations between the operators to the north of the Kanawha River and on the Kanawha & Michigan R. R. in the Kanawha fields and the scale committee of District No. 17 of the United Mine Workers were broken off, April 8, at a meeting held in the Sinton Hotel, Cincinnati, after conferences lasting several weeks. Operators of about twenty mines with an annual output of 5,000,000 tons were represented.

Attempts were made to have the union recede from its demand for the Jacksonville scale of \$7.12 a day, it being pointed out that the open-shop mines to the south of the river were working on a scale calling for \$4.68 a day. It is understood that the union operators were willing to go as high as \$5.50 a day in order that an agreement might be effected, but the miners were obdurate in holding out for the scale. It was announced that this precluded getting business in competition with the surrounding mines and rather than enter into an agreement, all of the mines affected would be closed down.

Coal Destined to Play Prominent Role In Reparation Settlement

Report of Dawes Committee Fraught with Deep Significance in Eyes of Washington—British and American Coal to Meet Competition from Large Volume Produced by German Mines

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

Directly, or indirectly, every individual in the world, from the naked savage in an African jungle to the richest industrialist in America, is affected by the existing reparations situation and will be benefited by the settlement which is expected to follow the reports of the committees of experts. Coal is destined to play a major part in any plan of settlement, since it is one of the few commodities that Germany can export in quantity.

The report of the Dawes committee is regarded in Washington as a decisive document. Sight should not be lost of the fact, however, that it is only a plan for settlement and not a settlement in itself.

A few think this report will mark only another weary milestone along the road from the armistice to normalcy, but the great majority believe that a plan has been devised that will be the basis for successful negotiations.

The great difficulty in the reparations tangle is to find means of payment whereby wealth from Germany may be translated into credit outside of Germany. There are some stocks of gold and silver in that country, but far less than is needed for essential reserves for its own financial structure. Liquidation of German assets in other countries has gone as far as it can. No means yet has been devised to lay hands on the much-discussed German bank credits abroad.

Germany Now Without Ships

Before the war Germany furnished a large service to other nations with its merchant marine, but it no longer is operating ships. As a result, the only way that Germany can pay is by exporting goods. The amount that can be paid must come from the difference between the value of these exports and the cost of the foodstuffs and the raw materials that Germany must import. The public, particularly the French public, has failed to appreciate that there can be no transfer of wealth to the Allies which can be made immediately available except as surpluses of goods are transferred.

There will be no great enthusiasm in the Allied countries for the throwing open of their markets to goods manufactured in Germany. It is evident, however, that if the German machine is to be set running again means must be found to absorb a large amount of German manufactured products. This means the displacing of a like amount of these goods which now are being furnished by other countries. As it would be highly unpopular to assist in the building up of German assets by that method, it is certain that a forced draft will be used in endeavoring to crowd out of Germany the maximum amount of coal and potash. Germany

has almost inexhaustible reserves of both of these commodities.

France particularly will be interested in encouraging large exports of coal. Her domestic coal industry is relatively small. The French realize that they could afford to seal up their mines and keep that resource in the ground for one hundred years, if necessary, while Germany would be building up credit abroad by the export of its excellent coal. The coal fields of the Ruhr are among the richest of the world. The seams are thick and occur, one above the other, in formation particularly easy to mine. Production in that region was growing at a very rapid rate. In all the demoralization and uncertainty of 1920 Germany, had she really wished, could have furnished to France the 2,000,000 tons per month provided for under the Spa agreement.

More Ruhr Coal Than France Needs

The Ruhr, however, is capable of furnishing much more coal for export than France can take, which will mean, it is predicted, that a great effort will be made to force this coal into other markets. This means the displacing of a large tonnage now being furnished by the British. Such export markets as the United States has retained will be subjected to double pressure as a consequence. France particularly must begin to receive reparation payments. The whole situation seems to indicate that a large volume of German coal is to be pressed upon the market, almost regardless of price.

It frequently is said facetiously in this country that the hazards of the coal business are so great, and the profits so uncertain, that no Jew is found in the trade. Evidently this is not the case in Germany, as Hugo Stinnes was the outstanding figure in its production and distribution. Being an industrialist, he opposed any great levy on German coal resources for the payment of reparations in kind. He would have burned the coal under German boilers and would have forced the world to absorb a flood of German manufactured goods. The hand of Death has swept Stinnes from the stage just at a time that plans are laid to make coal the chief factor in the transference of German wealth to the outside. Had Stinnes lived, he might not have been able to block this plan. His passing certainly will make the task an easier one.

Three-Year Pact in Wyoming

Mine workers and operators of the south and north Wyoming coal fields have ratified the Jacksonville agreement, effective for three years from April 1.

British Miners Reject Offer of Mine Owners But Will Not Strike

In a heavy ballot the British coal miners rejected by 16,258 votes the offer made by the operators in reply to the demand for better working conditions. The decision against acceptance was accompanied by a demand that the government institute an inquiry into wages in the mining industry, and it was officially announced that the Minister of Labor had agreed to appoint a court of inquiry to meet after Easter.

The agreement regulating wages and conditions in the coal fields expires April 17, but there is no question of a strike, and arrangements are to be discussed next week under which work can be carried on while the court conducts its inquiry.

Hoover Sees Key to Rate Cut In Consolidation

Testifying at Washington April 9 before the House Commerce Committee, which has been considering the Hoch resolution to direct the Interstate Commerce Commission to undertake a general rate revision, Herbert Hoover, Secretary of Commerce, said he believed an exhaustive study should be made by the commission to lay the foundation for a general readjustment of railroad freight rates.

"Simplification of the rate structure," he declared, "might be difficult under present conditions, but it probably would be shown that it could be done easily if there were consolidations of railroads. A thorough study of the rate structure undoubtedly would become one of the strong arguments for consolidation."

Mr. Hoover declared there was pressing necessity for a revision downward of rates upon such primary commodities as farm products, coal, iron and steel and lumber, but expressed the view that reductions might work a hardship on roads whose revenues come chiefly from carrying such commodities. Consolidation, he said, would tend to equalize the loss in revenue instead of making certain carriers stand the brunt of the reduction.

Before consolidation can be carried out on a wide scale, Mr. Hoover said, legislation will be needed, particularly to confine the power and attitude of the Interstate Commerce Commission toward them. If a definite policy as to grouping of roads is translated into law, the committee was told, there will be a marked tendency toward efficient consolidation.

Horizontal increases and reductions of freight rates, in the opinion of the Secretary of Commerce, have thrown the entire freight structure out of adjustment. He estimated that the cost of operating railroads and their revenues are 70 per cent above pre-war levels.

New York to Save Money on Coal This Year

Twenty-eight coal companies submitted bids on April 8 for furnishing and delivering between April 1, 1924, and March 31, 1925, more than 500,000 net tons of coal to thirteen municipal departments of the City of New York. When all bids had been tabulated Edward W. Buckley, Commissioner of Purchase, announced that the prices were from 50c. to \$1 per ton below last year's figures and that the coal bill for these departments for 1924 would be approximately \$250,000 lower.

The largest quantity called for in any one lot was for 160,760 tons of No. 1 buckwheat for barge delivery, for which there were seven bids ranging from \$4.51 to \$5.25 per ton. For delivering 43,980 tons of bituminous run of mine coal to the same points, the prices submitted ranged from \$4.29 to \$5.48. The schedules called for various tonnages to be delivered by truck in the various boroughs of Greater New York. Prices submitted for supplying No. 1 buckwheat ranged as follows: Manhattan, \$5.29 to \$6.21; Brooklyn, \$5.38 to \$6.03; Queens, \$5.21 to \$6.48; Bronx, \$5.48 to \$6.21, and Richmond, \$5.48 to \$6.24.

Tenders for furnishing and delivering soft coal, mine run, to various points in the boroughs ranged from \$5.69 to \$6.39 in Manhattan; \$5.24 to \$6.48 in Brooklyn, and \$5.22 to \$5.75 in Bronx.

For delivering 12,000 tons of bituminous coal to the Fire and Police Department boats the prices ranged from \$5.29 to \$5.97.

Stove and chestnut sizes of hard coal when delivered by truck to designated points will cost the city from \$11.49 to \$13.75 per ton and pea coal from \$8.21 to \$10.47, while barge delivery of stove coal will cost from \$10.47 to \$12.25 per ton.

For delivering coal in carload lots to the city institutions in Orange County the bids ranged from \$9.97 to \$12.09 for stove coal; \$7.38 to \$7.50 for pea coal; \$3.59 to \$3.74 for barley coal and \$4.86 to \$5.39 for bituminous mine run.

Bids received for delivering in carload lots 23,680 tons of bituminous mine run to pumping stations on Long Island ranged from \$4.86 to \$5.38, and for 15,800 tons of No. 1 buckwheat from \$4.81 to \$5.87.

May Defer Effective Date of Section 28

Chairman Hall, of the Interstate Commerce Commission, appearing before the Committee on Merchant Marine of the House of Representatives on April 11, urged that legislation be provided so as to defer until June 1, 1925, the effective date of Sec. 28 of the Merchant Marine Act. He made it clear that great confusion in transportation will result if the law is made effective May 20, next, as proposed by the Shipping Board.

Since it is practically impossible to obtain the necessary legislation prior to May 20, the prospects seem to favor the coming of the period of confusion which Chairman Hall pictures. The

Essen Miners' Band Plays At Stinnes Funeral

The famous coal miners' band of Essen took part in the funeral of Hugo Stinnes, at Berlin, Monday, playing dirges and Westphalian folksongs. When the news of his death reached the home town of the famous industrialist the leader of the band asked permission of the family to honor their dead chief by playing the miners' "taps" at the obsequies.

Some of the members of the band worked with Stinnes during his active apprenticeship in his father's mines and all learned to respect him as an employer. Stinnes was always a generous patron of the band and was especially fond of its rendition of his favorite native tunes.

Interstate Commerce Commission will not hesitate, it has been indicated, to postpone the effective date for a short period on the ground that it is physically impossible for the railroads to prepare their tariffs by that time.

The oral arguments which will begin before the Interstate Commerce Commission April 17, will be confined entirely to the extent to which the commission's authority goes in the matter of postponing the date on which Sec. 28 will become effective. It seems entirely improbable that the commission will be convinced that it has any latitude in the matter beyond a comparatively few days.

Coal has not come into the discussion before the Merchant Marine Committee. The railroads are firm in their decision to contend that low rates to tidewater are in no sense export rates. Their position is that the reduction is made primarily because of the lower cost in handling coal in wholesale quantities to dumping points at piers. The rates are held to have been made in the interest of the intracoastal movement and that the small percentage of this coal which moves to foreign countries is simply an incident.

The traffic executives of the railroads serving the Eastern territory have very carefully considered the interpretation and application of Sec. 28, and have decided that rates on coal and coke to the North Atlantic Ports, which are lower than track delivery rates on the same commodity to the same port for transshipment, are not included within the operation of Sec. 28, because such rates are not based upon contemplated exportation, but are based primarily on the incident of coastwise transportation to other ports of the United States. This will, of course, continue the present rate arrangement on traffic which moves coastwise and export from these ports and there will be no change as a result of the Shipping Board's action.

A bill has been introduced by Senator Curtis amending No. Sec. 28 of the Act so that it will not become effective until July 1, 1925. It is doubtful if this can be passed before the date set for Sec. 28 to become operative as it now stands.

Blame for Yukon Explosion Not Placed

In investigating the cause of the explosion at the No. 2 mine of the Yukon Pocahontas Coal Co., at Yukon, late in March, in which 26 men were killed, the coroner's jury did not fix the responsibility for the explosion on any particular individual or individuals. After visiting the mine and then examining fifteen or more witnesses, the jury brought in a verdict stating that it found from the evidence that the explosion started in Rooms Nos. 5 and 6 in what is known as parallel entry in No. 2 mine. In the opinion of the jury gas was ignited either by powder or an electric detonator, and an accumulation of coal dust extended the explosion.

T. J. Dawson, general superintendent of the Yukon-Pocahontas company, expresses the belief that the explosion was caused not by gas but by the explosion of powder, planted in two abandoned rooms of the mine. It has been stated by Mr. Dawson that electric detonators and fragments of a powder box were found in rooms Nos. 5 and 6, with a wire extending from the "planted mine" to a main entry switch.

The caps, found in a section of the mine where no work had been done for six months, were new.

It is now stated that the bodies of dead miners were found so far away from the center of the explosion that a volume of gas sufficient to blow the bodies for such a distance would have wrecked the entire mine.

Northwest Retailers Charged With Unfair Competition

The Northwestern Traffic & Service Bureau, its officers, directors and subscribers and the Northwestern Publishing Co., of Minneapolis, Minn., are cited in a complaint issued by the Federal Trade Commission charging unfair methods of competition in the marketing of coal. The subscribers of the Bureau, numbering approximately 1,800, are in large part retail coal dealers doing business in Minnesota, North Dakota, South Dakota, Iowa, Nebraska, Missouri and Kansas.

The complaint alleges that the respondents by co-operative means and methods prevent wholesalers of coal from selling in the territory served by respondents direct to consumers or to any other persons not retail dealers in coal qualified under the designations of "legitimate" or "regular" dealers as defined by the respondent organization. It is also alleged that the purpose and effect of respondents' co-operative methods were to control the price of coal to the consumer without interference from outside competition.

The following are officers and directors of the Northwestern Traffic & Service Bureau, and are named individually in the complaint: A. L. Havens, president; C. A. Cruikshank, vice-president; H. L. Laird, secretary-treasurer; H. T. Folsom, William Hardman, J. A. Young, F. N. Furber, C. F. Rourke, F. C. Potter, directors. I. C. Cuvelier, president of the Northwestern Publishing Co., also is named individually.

Problems In Underground Management

Suggestion for Regulating Flow of Air at Foot of Intake Shaft

Movable Triangular Framework Will Split Air Current Equally
or in the Proportion Desired—Current in Either
Direction Can Be Shut Off

BY HARVEY DABNEY
Harrisburg, Ill.

MANY air shafts are in bad condition, especially at the bottom. Here, in many cases old timbers, rock, etc., are piled, not infrequently obstructing the air and causing serious eddy currents and an inevitable loss of power. The device illustrated herewith is intended to take the place of a pile of rubbish in directing the air and at the same time to furnish an easy and effective means of regulating it in case the current divides at the foot of the shaft.

As may be seen in the accompanying illustration, this regulator is simple and can be built by almost any mine carpenter. It consists of an A-frame of heavy timber, say 6 x 6 in., resting

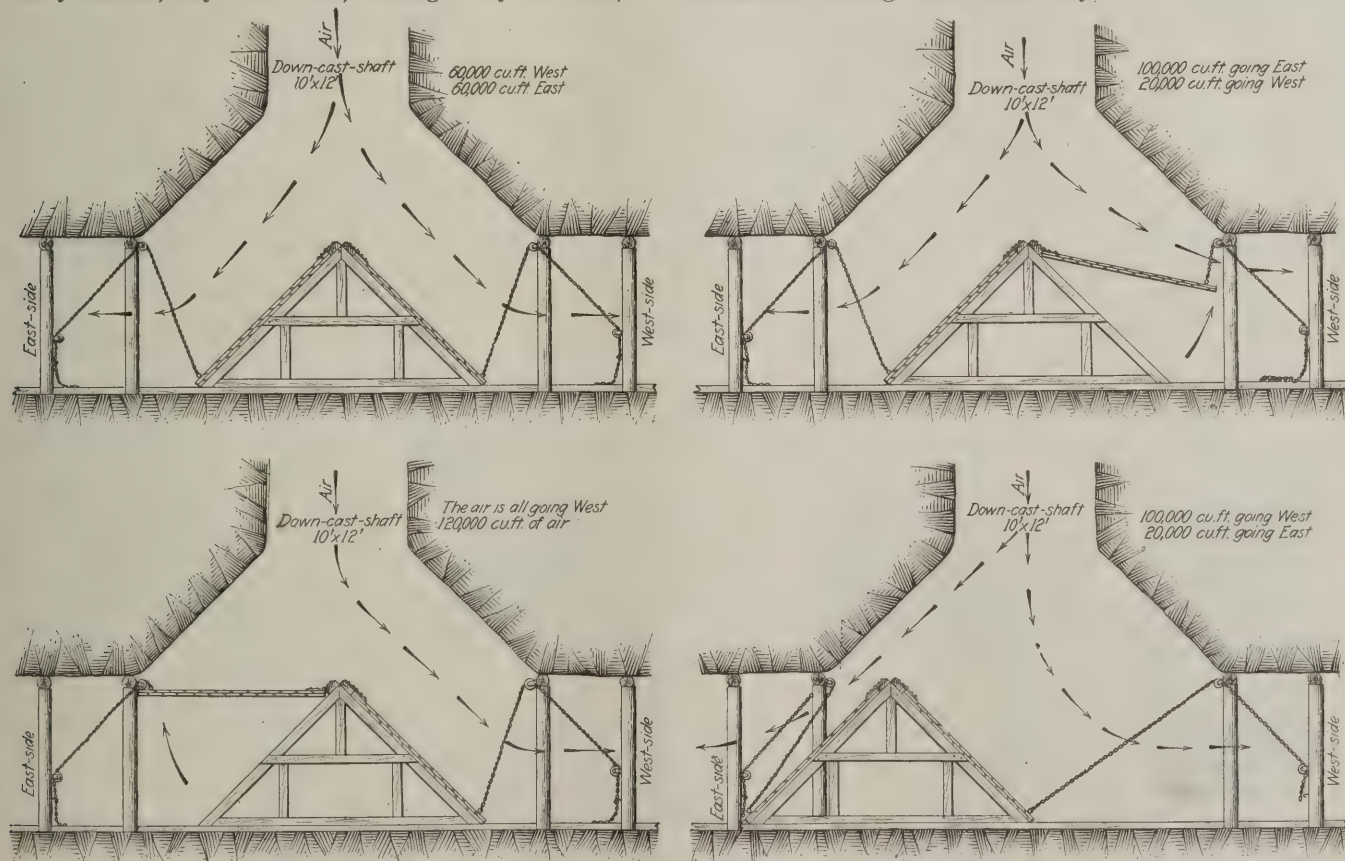

upon, but not attached to a set of sills. The frame may thus be moved from side to side of the air shaft or secured in any intermediate position. At the top of the movable frame two doors are hinged. These are made airtight and completely cover both sides of the A-frame. From their lower edges ropes or chains pass over pulleys attached to the cross timbers in the air courses extending on either side of the shaft bottom.

It will be seen that two means of regulating the flow of air to either side of the shaft are available. Thus a door upon one side of the A-frame may be lifted, in this manner choking

or throttling the air upon that side and allowing less of it to pass through. That same movement increases the quantity of air delivered to the other side. Again the whole A-frame may be shifted to one side of the air shaft, with the result that any desired volume of air may be made to take a path upon either side of the shaft, the limit of course being the total output of the fan.

In case a quick change in the regulation of the ventilating current is desired, the door should be raised, whereas if the division of the incoming current is to be more or less permanent, the position of the A-frame itself should be changed. Either means would be highly effective, but probably by shifting the frame the change would not be accompanied with so great a loss of power.

It would appear that this device offers a ready means of quickly regulating the flow of air to either side of the shaft bottom. It is simple in construction, inexpensive and would be easy to build and install. Once in place it should require little upkeep and should last indefinitely.

Easily Constructed Regulator for Installation at the Foot of Air Shaft

Raising one of the doors throttles the air going to that side and forces a larger proportion of it to the other airway.
Moving the A-frame to the side accomplishes the same result.

Practical Pointers For Electrical And Mechanical Men

Care and Adjustment of Cam-Type Controllers for Electric Motors

Operation Similar to That of Drum-Type Equipment—Circuits
Made and Opened by Small Contactors—Lubricant
Applied Where Air Is Not Too Dusty

THE general appearance of cam-type controllers and their method of mounting and operating are much the same as for controllers of the drum type. The latter have rotating cylinders with segments which make contact with fingers, whereas the cam-type controller consists of a shaft which carries a series of cams that in turn cause the closing of one or many contactors. Fig. 2 illustrates a contactor in the open position. It consists of a stationary element A, which may or may not be provided with a blowout coil and a movable element B, held open by a spring S, and closed by a cam C. The action of this contact is exactly the same as that of a magnetic contactor, and the same contacts are used. Figs. 2 to 4 show the three positions of the contact: First, when open; second, when just touching at the tip; third, when it is entirely closed, making contact at the heel. In opening, the process is reversed. This

rolling action from the tip to the heel and back again in closing and opening causes the arc to be broken at the

tip and the current to be carried at the heel. By using a rolling instead of a sliding action, in closing, mechanical wear is eliminated and much heavier contact pressures can be used.

The current is carried from the movable contact to the terminal by means of a flexible shunt. One end of the spring is insulated so that no current can pass through this member. Because the spring is a considerable distance from the contact, it is not directly affected by heat from the contact or arcing, and is, therefore, in no danger of having its temper drawn.

Various combinations of switches can be obtained by changing the number of contactors and the shape of the cams. The length of the frame can be adapted to any desired combination by changing the length of the insulating bars and the sheet-iron cover. The following points should be observed when inspecting a cam controller:

(1) The contacts, when closing, first touch at the tip or upper edge and roll until the current-carrying contact is made and the heels touch. The reverse action should take place when opening. Examine the contacts to see that they act in this manner, and see that they engage throughout their entire width

when they are in their final closing position.

(2) Do not file the contacts, for the wear in operation improves their surfaces by eliminating the minor high spots. Ordinarily, a contact will carry more current after it has been "worn in" than when new. If the action of the contact is correct, the burning should all take place at the tip.

(3) When the contacts have burned back so that the arcing occurs close to the heel, both contacts should be renewed. Do not attempt to use an old contact in combination with a new one.

(4) Do not lubricate the contact surfaces. They are so designed that there is but little rubbing, making lubrication unnecessary. Oiling the contacts would not be well, for dirt always accumulates on lubricated surfaces. The roller pin, hinge pin, and camshaft bearings will operate to better advantage if lubricated a little unless the air is very dirty. Lubrication tends to hold dirt in the bearings, and under some conditions they will operate better if dry.

(5) Measure the contact pressure with a spring balance. For various types and sizes the manufacturer should furnish a table showing the normal contact pressure. This should be maintained if the best operating conditions are to be attained. A low pressure will increase the heating, and a high pressure will make the controller hard to operate.

(6) The controller notches are indicated by a ratchet wheel. In many controllers the pressure of the roller on the ratchet wheel can be adjusted. The operation of the controller often

Figs. 1 to 4—Illustrating Manner in Which Cam-Type Controllers Operate

Fig. 1—Controller with radial handle. Fig. 2—Contactor resting against low radius of cam, contact wide open. Fig. 3—Cam partly turned, toes of copper tips touching together. Fig. 4—Long radius of cam holds contact securely closed. The last three illustrations clearly demonstrate the method of operation and show how smooth action is obtainable by the use of the cams.

can be materially improved by the careful adjustment of the ratchet spring. Where the air is free from grit, the ratchet wheel and roller should be lubricated. Examine all the bolts to see that they are tight. This is particularly necessary on bolts that hold the contacts, shunts and terminals in place. A loosening of any of these bolts may materially increase the heating.

(7) If the controller is exposed to corrosive fumes which discolor the copper parts, it will be necessary to clean the contact with fine emery cloth or sandpaper, and occasionally the current-carrying joints may have to be disconnected and cleaned. Sometimes covering these joints with a thin coating of solder, called tinning, will prevent corrosion.

(8) The controller should be cleaned out from time to time, depending upon the rapidity with which dirt accumulates. A convenient method is to use compressed air at low pressure. Do not subject the controller parts, particularly the insulation, to a high-pressure air jet, as this may injure the insulation.

Both drum-type and cam-type controllers can be provided either with a rotating or with a lever handle. They may also be mounted vertically on the

rear of a panel and operated by a hand-wheel through gears and chains from the front. If the controller is mounted on the back of a panel with the shaft horizontal, it can be extended directly through the panel without the use of gearing.

Cam controllers are frequently built motor-operated. The construction of the controller is the same as for manual operation, the handle being replaced by a reduction gear and pilot motor.

The drum controller is more compact for certain switching combinations, such as reversing. On the other hand, the cam is more easily designed for complicated switching, and new combinations can be more easily made as they can be accomplished by using cams of different shapes, whereas in the drum design new drum castings are usually required. The cam units can be removed individually without dismantling the controller. The same is true of the contact fingers of drum controllers. It is usually necessary to take the drum out of the controller in order to replace any of the drum segments, and after replacement, these segments should be trued up in a lathe.

Control Engineer.

Westinghouse Electric & Mfg. Co.,
East Pittsburgh, Pa.

How Relief Valves Prevent Breakage of Pumps

Opinions differ as to whether a relief valve should be installed on the discharge line of a plunger pump. However, experience has proved that it is undoubtedly necessary where the pump is discharging into a long, high column line which exceeds 50 per cent of the rated foot-head capacity of the pump or where the suction line may collect much air.

Many pumps are broken by momentary high pressures built up in the pump during some abnormal condition which usually exists for but a short time. The most feasible explanation of these high pressures and of the accidents they cause is that the pump takes in air which is compressed with each stroke of the plunger; this causes the water in the column line to stop flowing. Finally, when the pump has built up enough pressure under the discharge valves to equal the weight of the water on top of them, the whole discharge column of water starts moving instantly. Previous to this time, the pump will be operating at its maximum speed and the result is that a high pressure is suddenly built up.

I have known several cases where pump breakages were frequent until a relief valve was installed on the dis-

charge line. The usual practice was to set the relief valve at a pressure about 25 lb. higher than that normally required in the column line, thus relieving abnormal pressures before they became unduly great.

I remember an instance where a pressure gage was installed on a 7x8-in. triplex pump. This pump had a suction line about 700 ft. long and a discharge line about 300 ft. long. Normally the gage showed a pressure of 140-lb. per square inch but occasionally, for some unknown reason, the pressure gage momentarily registered as much as 600 or 700 lb. In this particular installation a tee connection on the suction line led to a short piece of pipe which ran to another sump at the foot of the hoisting shaft.

We noticed that if the gate valve

located on this short suction line was suddenly opened while the pump was operating at full speed on the regular suction line, the pressure on the gage suddenly increased practically as has just been described. We came to the conclusion, therefore, that the pump was ordinarily getting much air with the water in the main suction and that when the short suction line was opened the pump received a full supply of water which caused a sudden increase in pressure. After a 3-in. relief valve was put on the line the pump operated satisfactorily, whereas prior to that time many valve chambers and connecting rods had been broken.

When acidulous mine water is being pumped the relief valve is rapidly destroyed by the corrosive action of the water. This causes the valve to leak and give trouble. In such cases it is advisable that a relief valve be placed as shown in the illustration on the end of a vertical section of pipe connected to the discharge line. If the valve is not allowed to leak, a cushion of air will form directly under it, thus preventing any water from coming in contact with the valve seat, except when the relief valve opens to relieve abnormal pressure.

When the discharge line does not have a check valve, the relief valve will also take care of the back surge when the pump is shut down.

E. E. KENDALL.

How Thermit Welding Is Done

Thermit welding is primarily a casting process used mostly for repair work where considerable metal is to be deposited. In the electrical repair shop it is frequently used for building up broken motor frames, heavy truck castings, bumpers and side plates. An intense heat is generated by a chemical combination of aluminum filings mixed with oxide of iron and primed by a magnesium powder.

Keep Locomotive Armature Bearings Clean

The commutator and armature bearing is ordinarily protected by a dust cap over the end of the shaft. This cap is made of sheet steel or malleable iron and is fastened to the housing or bearing by bolts or screws, thus completely enclosing the bearing. The dust cap should always be kept in place because the position of the bearing with respect to the wheel flange is such as to permit dirt, sand and wheel-wash from the flange to be thrown directly on this part of the motor.

The outer extremity of the pinion end bearing usually extends into the gear case and needs no further protection. The gear case fits over the armature bearing or an extension of the housing snug enough to keep the lubricant in the case. This tends to keep the dirt out of the bearing at this point. There is little possibility of dirt getting into the armature bearing from the inside of the motor because the oil-throwers on the shaft and the oil-catchers on the housings act as guards and give ample protection against the entrance of dirt.

Relief Valve Saves Pump from Abnormal Pressures

Before the pressure can rise to a point where it might throw unusually heavy stresses on any part of the pump or pipe line, the relief valve opens. Such an arrangement will cushion slight surges even during normal operation. The vertical pipe under the relief valve acts as an air dome.

Somnolent Condition Pervades Coal Markets; Contracting and Lake Preparations Tardy

Anxious to think of something pleasant in the midst of the depressing gloom that overhangs the soft-coal markets of the country, many producers are casting a hopeful glance in the direction of the lakes as the navigation season approaches. Hoping, like Micawber, that something eventually will turn up to dispel the prolonged dullness is the daily occupation of the trade—more favorable freight rates are the expectation of some while others look to the lake movement. The rate matter is yet to be threshed out in Washington, beginning next week, and the actual season of lake navigation is still some distance off, but the preliminary activities have been disappointing, bookings and arrangements being meager. Contracting also continues to lag, many large consumers showing a disposition to watch for bargains in the open market rather than tie themselves up to agreements.

Coal Age Index advanced 1 point to 172 as of April 14, the corresponding price being \$2.08. This compares with \$2.07 on April 7.

Small Sizes Stiffen in Midwest

With the general falling off in domestic business and increasing shutdowns of mines in the Middle West fine coals are on the upgrade, screenings showing a slow but steady firming up. Whereas more than 3,000 cars of lump, egg and nut stood at Franklin, Williamson and Saline County mines without bills, every load of screenings was shipped without delay. Even railroad business has slumped in the Carterville field, where the mines still running are getting only about two days a week, and it is worse in the Duquoin and Jackson County field. The Mount Olive and Standard fields also find the going hard.

Unsettled labor conditions have put the Kentucky markets in a fretful state. Despite price cuts to encourage early stocking, business has been light in

Louisville. Trade is slow in western Kentucky also, there being practically no production of block or prepared sizes; this has tended, however, to cause prices for nut and screenings to be firmer. The heavy carry-over on the Northwest docks has deadened the market there to such an extent that even price cuts have little effect. Somnolence reigns at Milwaukee. Mines in the Southwest remain idle, the deadlock in wage negotiations at Kansas City being unbroken.

Ohio Markets Scrambled

Conditions in the Ohio markets are somewhat mixed, there being signs that the bottom has been reached in Cincinnati with the placing of railway contracts, though early lake business is lacking. Dullness and pessimism reign at Columbus and Cleveland. Production is very low in the Pittsburgh and central Pennsylvania districts. New England just plugs along at the recent low level. Atlantic seaboard markets show a tendency to steady somewhat, though a feeling of disquiet is evident at Philadelphia.

Production of bituminous coal took a pronounced drop during the week ended April 5, when output, according to the Geological Survey, amounted to 6,814,000 net tons, which was 2,004,000 tons less than was produced during the previous week. This is the lowest output on record for an 8-hour day week, except during the 1921 depression. The decrease was due in part to observance in union districts of the Eight-Hour Day, April 1, and in part to a large number of mines being idle. The total output for the coal year ended March 31 was about 542,000,000 net tons, compared with 427,598,000 tons in 1922-1923. Production of anthracite during the week ended April 5 was 1,548,000 net tons, a decrease of 394,000 tons compared with the preceding week. Total output for the coming year was about 96,000,000 tons, compared with 46,486,000 tons in 1922-1923.

Midwest Screenings Stiffen

The one thing that helps relieve gloom in the Midwest these days is the slow but steady firming up of screenings. Fine coals of all central western fields are on the upgrade, due to the general and almost complete collapse of domestic business and the shutdown of more mines. The total volume of coal produced was light indeed during the past week in Illinois and Indiana and practically nothing moved except the smallest sizes. More than 3,000 cars of lump, egg and nut stood without bills at the mines of Franklin, Williamson and Saline counties while every car of screenings left the mines immediately.

Southern Illinois screenings moved up from \$1.90 to an average of \$2.15, with some placed at \$2.25, and the price steadily bracing. Indiana No. 4 followed. Central Illinois screenings touched \$2 before the end of the week although most of it sold at \$1.80@1.90. Practically none was available, however. In another week it is expected the price will reach a point that will start the crushers working on domestic sizes now cluttering the tracks.

Some anthracite is moving to Midwest dealers following the price cut of April 1 because most dealers think it is rock-bottom for this summer and they might as well put in a little to handle the light early-summer trade.

The Illinois mining fields are full of "no bills" and miners' pessimism. In the Carterville region the few mines that are still open are getting only about two days a week. There is a slump in railroad business in this territory. In the DuQuoin and Jackson County fields conditions are worse than in the Carterville field, and prices are lower, with no railroad tonnage at all to speak of. The Mount Olive district is having a hard time. There is practically no domestic coal moving and the mines are not producing steam sizes in volume enough to take care of their customers. The Standard field is plugging along on from one day to three days a week. Railroad tonnage is light. Prices are below cost of production and the situation is an unusually unhealthy one.

Spring weather has put a sudden end to all activity in St. Louis retail coal yards. The dealers are making an effort to get early spring business started, but the public is slow in responding.

There is a little steam wagonload business, and carload steam and screenings from all fields is unusually good, with fairly good demand for the smaller sizes of nut. Country steam business is slowing up a little, but country domestic has dropped off entirely, with the exception of a little demand for chestnut anthracite.

New retail prices in St. Louis effective April 10 are:

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924	1923
Index	172	235
Weighted average price	\$2.08	\$2.84

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Standard, \$5; Mount Olive, \$5.50; Carterville, \$6.75; Granite City byproduct coke, \$8.75; Elkhorn byproduct coke, \$10.75; St. Louis gas coke, \$10.25; Anthracite, chestnut, \$16; egg and stove, \$15.75; grate, \$15; Arkansas anthracite, \$13; West Virginia smokeless lump and egg, \$11.

Kentucky Does Little

Coal trade in Kentucky was light indeed during the past week, in spite of price cuts to induce early stocking. The steam trade still has a good deal of coal left over and the domestic business is saturated. This means that nothing will be doing until some real steam demand appears. Thus far it has merely been whispering. However, lack of production has stiffened up steam prices somewhat, as in other fields. The whole producing industry of the state remains in a state of fretfulness over the swing to non-unionism in the eastern end and the likelihood of a strike or open-shop outcome of negotiations in western Kentucky.

In an effort to interest domestic consumers in early stocking, prices in Louisville have been dropped from 50c. to \$1 a ton, putting the price of best West Virginia coal, delivered at retail, to \$7.25 a ton, with eastern Kentucky lump \$7; western Kentucky lump \$6; smokeless \$9; coke \$12; anthracite \$18.50; cannel \$10; blacksmith \$8.

The western Kentucky market is very slow with practically no production of block coal or prepared sizes. This results in screenings as well as nut coal being much firmer in price.

Between bad weather, clay slides, standing water, and low prices, it is reported that only the larger strip mines are operating.

Northwest Trade Remains Flat

Nothing livened up the trade of the Northwest during the week. The carry-over coal on the docks—estimated by the Northwest Dock Operators' Association to be 1,400,000 tons as compared to only a few thousand tons last year—has a deadening effect on business and cuts in prices do not revive it. Industries and inland consumers are not buying anything to speak of and the domestic trade is satisfied. The main interest among dock men nowadays is: Will there be any change in freight rates off the docks to make it possible for the docks to do business this year. Very little coal seems to have been contracted for movement up the Lakes yet, though the opening of navigation is at hand.

The Milwaukee coal market continues in a state of somnolence. The cut of 50c. per ton in hard coal met with little response in the way of increased demand, as the weather continues mild. Soft coal is lifeless, prospective buyers holding off for the promised May reduction. Screenings and the cheaper steam coals are in fair demand for immediate use.

The mines through Kansas, Oklahoma, Arkansas and Missouri remain idle while the deadlock continues in the joint conference of scale committees in Kansas City. The small surplus of screenings which had accumulated when work was suspended April 1, is exhausted, and the surplus of domestic grades is rapidly melting.

The coal market in Colorado slowed down considerably last week due to warm weather, which has been prevailing throughout the mountains and eastern slope region. Mines worked on an average of three days last week and a number of unconsigned loads were reported on track. Prices are unchanged.

In Utah domestic consumption has fallen off, due to weather conditions. Industrials are demanding less slack, which is enabling operators to catch up on their orders for this grade. Retailers are buying little and stocks in Salt Lake City are lower than they ever were. Utah working time is around two days a week. Labor conditions are satisfactory.

Cincinnati Begins to Look Up

Many signs at Cincinnati point to the fact that consumers are beginning to realize that the market has about hit bottom. One is found in the letting of railway contracts. The price list of the past week showed such a tremendous spread that the sales offices have been panicky and the buyer completely up in the air. Lake people are not venturing on this market, preferring to lay off as long as possible so that any buying orders that they might have will not favor an upward or stabilizing movement. Local offices are holding well to the circular on Pocahontas and the mines are holding down production to make the condition fit. New River and the off grades are a bit lower, some of these making \$3@3.25 price on lump and egg and \$2 on run of mine. Specialized coals are quoted as follows: Egg, \$2.25@2.75; block, \$3@3.50. Quotations and concessions do not interest the buyer, however, for he cannot digest more than is being put on the market. River business is booming along at a better rate than for some time.

Unrelieved dullness prevails in the Columbus market. Trade in both domestic and steam is quiet, only a minimum tonnage moving. Producers and distributors expect the quietude to continue until lake trade is under way. Little demand for Pocahontas or other smokeless grades is reported and splints also are quiet. Production in Ohio fields shows that domestic lump demand is almost nil. Contracting for steam tonnage is quiet. Many of the larger consumers are content to buy in the open market while prices are low in preference to entering into agreements. Public utilities are buying slightly more, while the railroad demand is steady. Little is doing in the Lake trade.

Pessimism is the keynote of the coal trade at Cleveland. Consumption is at a minimum and stocks continue to be sufficient to take care of present needs. Mines continue to close down, nearly half those in eastern Ohio now being idle, and those still running are lucky to get half time. Lake boats are doing some shifting to take on coal cargoes, but it probably will be some time before any coal carriers leave for the upper Lakes. Loading in this trade is not as heavy as it was last April, and there has been a steady increase in stocks.

The coal market at Buffalo is unchanged. Operators and jobbers alike are steeped in gloom.

Production in the Pittsburgh district is down to about 30 per cent of rated capacity. Prices in the spot market are unchanged. Expiration of contracts has brought little if any increased inquiry in the spot market. There do not seem to be even any negotiations for lake coal.

Production in central Pennsylvania is at the lowest ebb for a number of years and prices are below the point of profitable production.

New England Just Slogs Along

In New England the steam-coal market shows no improvement. There is enough tonnage being forced on reluctant buyers to keep reserves about on the level of a month ago, and only in few instances is there anything approaching comprehensive buying. Factors with rehandling plants of their own keep their stocks large to relieve pressure on Hampton Roads, and both on contract and on spot sales they are leaving no stone unturned to place enough coal to make room for weekly arrivals. Receipts all-rail as well as by water have diminished since April 1, and the number of contracts in force, especially by the rail route, has been materially reduced.

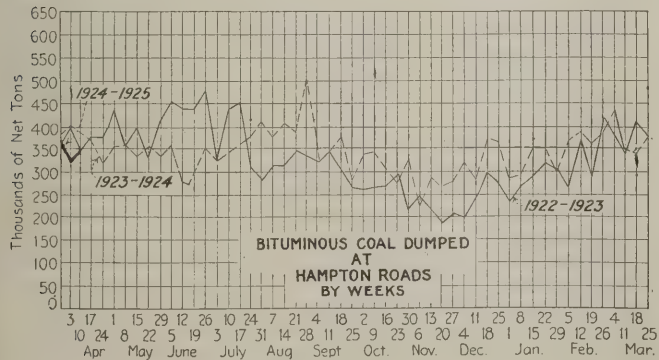

In certain cases the smokeless interests have curtailed output, but there remain enough in the open market to continue lively competition for what business offers. Prices f.o.b. vessel at Newport News and Norfolk therefore are in no wise improved; several agencies apparently are keen for orders at from \$4.15 to \$4.25 for Pool 1. Navy standard grades. There have been reports of distress coal sold much lower than this, but no one in the trade expects to pick up any considerable quantity even of No. 2 coal at less than \$4. Similarly, prices on cars at Boston have gone to \$5.25 under pressure, but the bulk of what is being sold on the spot market returns \$5.50, and in some cases a little more.

All-rail the situation is rather different. Aside from a few operators who are striving to keep their mines running the industry as a whole is proceeding cautiously with respect to future deliveries. In other words, there is a disposition to keep coal in the ground unless mines can be operated at a profit, and while perhaps under current conditions it will take some time to derive any benefit from this policy it is certain to result in improved conditions, at least in some markets. A shortage of output in central Pennsylvania would hardly affect trade in this territory except in a restricted sense, but somewhat higher prices than now prevail would give distinctly a better tone and permit firmer quotations on Pocahontas and New River.

Atlantic Seaboard Markets Steadying

The market at New York is gradually getting down to a steady basis. Demand is about the same on both line and at tidewater. Buyers want bargains when they want coal. With less coal mined, producers look for a steadier demand and possibly firmer prices. Continued inroads are being made in the large reserve piles, but this reduction depends largely on industrial conditions. Conditions at tidewater are slightly better than last week. Receipts were curtailed and there is not so much distress coal available at low prices. A few contracts are being signed, but at low prices.

Disquiet is evident at Philadelphia, as business displays little improvement. The labor question is far from settled, the union fields feeling that they are practically out of the trade, for most of the coal going to market is non-union. The general consumer is making no move to replace stock, many buyers holding off in the hope of saving some money on the price if they delay until midsummer.

Business at Baltimore has been demoralized by an output far in excess of consumption and demand, sales prices being below the actual cost of bringing the coal to the surface.

Production in West Virginia is greatly restricted in both high- and low-volatile territory, owing to extremely sluggish demand. Kanawha production is not over 30 per cent and Coal River production about the same but Logan mines are keeping up to about 60 per cent. New River, Pocahontas and Winding Gulf mines all have cut down operations, with the bulk of the tonnage moving being applied on contract.

Steam coal continues to be in scant demand in the Birmingham market, inquiry being light for spot coal and no great amount of interest being manifested in contract renewals among industrial consumers. The Louisville & Nashville R.R. is understood to have closed for its requirements from this field for the next twelve months, aggregating approximately 1,000,000 tons.

Anthracite Trade Settles to Even Basis

The spurt in the hard-coal market at New York following the announcement of the new prices, which are for the month of April only, is about over and demand has settled down to an even basis. Producers have enough business booked to assure them of a steady output for some weeks to come while the smaller independents are able to move their product without much trouble. Heavy buying by city departments during this and next month will provide an outlet for a heavy tonnage of the large sizes, especially broken, which is used extensively in the school houses and for which bids were opened on April 14. For the regular trade stove coal continues to head the list, with egg following. Pea coal moves steadily but at low figures for independent product. The steam coals are in fair demand. Rice and barley move steadily and without much trouble, some of the smaller producers having none to offer. Buckwheat is not so easily moved.

The anthracite trade at Philadelphia lacks the snap that was expected. Of course on the side of the producers conditions are better than during the last days of March, but no shipper has orders very far ahead. Stove is most in demand and most shippers are behind on it, but chestnut is quite plentiful and some independents have it in surplus, Pea has taken quite a turn for the better and there is very little free coal offering. Egg also is an easy size, but is moving fairly well. Steam trade is quiet, and even barley is in surplus with some of the independents. Buckwheat is particularly heavy and it is not unusual for this size, as well as rice, to be standing in cars at the mines awaiting consignees. The companies are putting both buckwheat and rice in the storage yards.

Coke Demand at Low Ebb

Coke demand in Connellsville is extremely slack, but prices show no further decline. Production of beehive coke during the week ended April 5 was 281,000 net tons, according to the Geological Survey, a decline of 15,000 tons from the preceding week. This is the fourth successive week that output has declined.

Foreign Market And Export News

British Market Quieter with Firm Undertone; Output Drops

The Welsh coal market has quieted down somewhat but is still notably firm. The recent agitation among buyers, both foreign and domestic, seems to have run its course, and this, coupled with the fact that in many quarters it is believed that the miners will not strike, has relieved the pressure. Aside from long-term contracts, all current business extends only over the next two weeks, beyond which period there is very little activity. German demand has sunk to a negligible quantity, but French business has improved with the recovery of the franc. There is a little business with Belgium and Holland, but not enough to make the operators anxious about fulfilment. Large quantities are ready for shipment to Italy, South America and coaling depots as soon as shipping is available.

The demand for anthracite is steady, though some kinds are very irregular.

The inquiry at Newcastle both from domestic and foreign consumers is heavy, especially for steam and gas coals. French, Swedish and Norwegian railways have bought over long periods and at prices which are very little below those now current. A fact which has perturbed British operators is that the Swedish railways have bought from Germany at lower prices.

The Egyptian Government is inviting tenders due May 14 on 150,000 tons of coal for delivery beginning June. It also has requested offers for 40,000 tons of American coal.

The miners' ballot is believed to be against acceptance of the operators' terms, but a substantial minority is favorable. The national executive committee of the Scottish Coal Miners' Union is recommending all Scottish members to reject the offers of the mine owners. The union leaders declare no intention of striking on April 17, when the present agreement expires, but may hold another ballot on the question of strike.

Brisk Trade at Hampton Roads; Market Tone Firm

Business at Hampton Roads is more brisk, with all unusual surplus removed from tide and prices slightly on the incline. Absence of contracts was one of the features of the market, the general run of consumers and retailers preferring to depend upon the spot market for supplies.

Coastwise trade is fairly active and overseas shipments are holding their own, with bunkers good and all piers reporting normal movement. The outlook is somewhat better, shippers predicting normal conditions during the next few months.

The tone of the market is firm, with reports from the coal fields that fully one-third of the operations serving this port have closed down temporarily, due to a rather uncertain market and a tendency to overproduction.

French Coal Market Notes Slackened Demand

Demands for industrial coals in French markets has slackened. As the difference in price between British and French coals is still very large, there has been a revival in the consumption of the latter and the Nord and Pas-de-Calais output is sold for several months ahead. Activity in household fuel has relaxed but is still higher than usual at this time of the year.

At a meeting of French and Belgian producers of house coals, to discuss summer prices, the French collieries decided that the present prices would be maintained up to Oct. 1, providing the summer premiums would be progressively deducted on the following basis: 5 fr. from April 1 to the end of May, 3 fr. in June and July, 2 fr. in August, the tonnage premiums to be unchanged. The Belgians, on the other hand, decided to leave prices as they actually stand up to the end of April,

in anticipation of a change in the position of the coal market in the event that the British miners strike.

Imports of British coals have been rather heavy of late and prices have gone up 1 to 2s. at the shipping docks.

Receipts of indemnity fuels in March are believed to have totaled between 850,000 and 900,000 tons for the month. The Office de Répartition des Cokes Allemands received coke from the Ruhr at the rate of 12,310 tons per day during March, which is about on the level of before the occupation.

News Items From Field and Trade

ARKANSAS

Several of the mines in the Spadra coal fields opened again the last week in April after having shut down, presumably until June 1. A protracted coal spell in the north created more demand than was anticipated.

CALIFORNIA

California coal development is reported on the increase. One of the recent activities is that of the Calcoal & Iron Co., of which H. C. Haas is president and W. Warner Thayer secretary, on 2,300 acres of coal land in southeastern Monterey County between Paso Robles and Coalinga.

ILLINOIS

Fifteen men were more or less seriously injured April 10, when a double-deck cage dropped 50 ft. to the bottom of the shaft at the Kathleen mine, at Dowell. The failure of the safety dogs on the hoisting drum to function when the fuse blew out on the electric man hoist caused the drop. The fact that a miners' train bringing additional men to the shaft was late probably saved a greater number from being injured. Several of the injured suffered broken legs and other hurts, but none is considered in danger of losing his life. The mine is operated by the Union Colliery Co., of St. Louis.

INDIANA

Indiana's state institution coal bill will not be as high this year as it was last, it is indicated by bids now being tabulated by Fred B. Robinson, secretary of the state purchasing committee, but the question is whether the bids on about 170,000 tons are low enough even if they are lower than last year. The committee will meet soon to determine this. In 1923 the state bought mine run coal for \$2.40 a ton; egg size, \$2.60, and screenings, \$2.05. Most of the coal bought came from the Fourth Vein.

James D. Sisson, owning the Dixburg hills, near Hazelton, has leased coal rights on part of the property to William Dempsey. It is understood that Mr. Dempsey has decided to begin operations within thirty days.

Committees are preparing for the mine-rescue and first aid meet of District No. 11, which will be held in Princeton June 28. The meeting will be similar to that held at Sullivan last year. It is understood that all the Indiana mines will close on that date, the first time such action has been taken by the Indiana mine operators.

Work of mines in the Terre Haute-Clinton field, gradually decreasing for the past few weeks, took a decided slump last week with the closing down of five mines in subdistrict No. 4. The Submarine, Talleydale, Clovally, Pine Ridge and Grasselli mines closed for an indefinite period, Talleydale closing to make extensive repairs. While many of the mines are closing down, a few are reopening, but the per cent of the latter is vastly less than of the former. Blackhawk mine, which was down for several weeks, was scheduled to resume work last week. Talleydale is closing down for repairs, for a period of about six weeks, it is said. The Fort Harrison Mining Co., which owns the mine, is expected to improve the Badyke mine in the same manner after the improvements in Talleydale are completed.

KANSAS

Directors of the Central Coal & Coke Co., at a meeting in Kansas City, March 20, voted to suspend the regular quarterly dividend due April 15 on both preferred and common stock. The suspension was attributed to the heavy cost of preparing for new lumber production in the West and to conditions in the coal industry throughout the Southwest.

KENTUCKY

A suit has been filed in the U. S. District Court at Covington by the Harvey Coal Co., of Perry County, against the Hazard-Jellico Coal Co., asking that a receiver be appointed to take charge of the defendant company's business. The Harvey Coal Co. leased coal land near Lost Creek to the Hazard-Jellico Coal Co. on May 27, 1919, at an annual rental of \$36,900 for a period of ten years. The petition charges that the provisions of the lease have not been met.

MARYLAND

Operations at the Big Vein mine of the Maryland Coal Co., which has been closed down for nearly a year, were resumed on April 10 with a force of about 75 men. According to an announcement made by Elkins Read, general manager of the company, the scale of wages will be about on a par with that generally prevailing in the Georges Creek region, the rate for pick mining to be 90c. and that for day labor \$4.64 per day. This company has one of the larger operations in the Georges Creek field but has not been operating regularly in the immediate vicinity of Lonaconing for several years. Still the mines are in fair condition notwithstanding such idleness.

MINNESOTA

F. G. Prest, director of purchases for the Northern Pacific Ry., Railroad Building, St. Paul, is taking bids until April 18, for furnishing fuel for that railroad, one set of bids for the section between Mandan, N. D., and Helena and Butte, Mont., and the other from Helena to the Pacific Coast. The first section calls for from 600,000 tons to 1,200,000 tons of lump and from 95,000 tons to 220,000 tons of sized washed nut, 2, 3, 4 and 5. The section to the west requires from 1,400,000 tons to 2,000,000 tons of mine run.

NEW YORK

Plans have been made for the retirement of all outstanding prior preference stock of the Burns Bros. Coal Co., New York City. The company is offering 120 for the stock and is taking it as fast as it can be acquired either in the open market or from individual owners. Last year plans for a readjustment of the company's capital structure were frustrated by opposition from holders of the prior preference stock. Officials are quoted as saying that rumors that the prior preference stock is being retired for the purpose of paving the way to readjust the capital structure are premature.

On May 1 the National Industrial Conference Board will move from 10 East Thirty-ninth St. to the fourth floor of the Park-Lexington Building, New York City. The board, which acts as the research organization for more than 30 of the largest associations of manufacturers in the country, was organized in Boston, in May, 1916, and for four years occupied quarters in Beacon Street with a small staff. Its New York offices were occupied in 1920, and at present it has more than 100 persons actively engaged in industrial research work in its headquarters, its branch offices in Washington, and in the field.

The report of the Pennsylvania Coal & Coke Corporation for the year ended Dec. 31, 1923, shows consolidated net income of \$741,704 after depletion, depreciation, federal taxes, etc., equivalent to \$4.29 a share earned on \$8,630,300 capital stock, par \$50. This compares with \$510,807, or \$4.14 a share, earned on \$6,164,500 stock outstanding in 1922.

OHIO

The coal-mining properties of the Blackburn Coal Co. located in Springfield Township, Jefferson County, will be sold at public auction by the receiver, James R. Hinchliffe, 1026 Guardian Building, Cleveland, on April 22. The properties consist of nine parcels of coal-mining lands, complete machinery and equipment, electrical railways and trackage etc.

The Vincent Coal Mining Co. has taken over the offices of the Blue Ash Coal Co. at 1820 First National Bank Building, Cincinnati, with George S. Payne in charge. The headquarters of the company is in Portsmouth and the move is the result of the acquisition of certain properties of the Doeppke interests.

The McMyler-Interstate Co. has been awarded a contract to install car-dumping machine for the New York Central R.R. for its projected \$1,000,000 coal handling pier at Ashtabula. The machine will cost approximately \$500,000 and will be of the most modern type.

John J. Moore, long connected with the Thomas Elevator Co., Chicago, has resigned his position to go with the Day & Maddock Co., Cleveland, Ohio.

PENNSYLVANIA

Seventy-five members of the Knickerbocker company's safety personnel were entertained at a banquet in the Fort Stanwix Hotel, Johnstown, April 10, as the guests of Superintendent R. A. Suppes. The Knickerbocker mines embrace the Telford, Jasahill and Wilbur operations. Warren Shumaker acted as toastmaster and safety addresses were made by Sheriff Martin Markle, of Somerset County; George Playez, superintendent of Jasahill and Telford No. 1 mines; D. Q. Williams, superintendent of Wilbur Mines Nos. 5, 6 and 2; Gordon Francis, superintendent of Wilbur mines Nos. 1, 3 and 4, and William Beahm, foreman of Jasahill mine No. 1. The host, General Superintendent R. A. Suppes also delivered a fine address.

A state charter has been issued at Harrisburg to the Bridgeville Coal Co., mining and producing coal and buying and selling coal, Bridgeville; capital \$25,000; President, Charles F. Brozier, Findley Avenue, Scott Township, Allegheny County. Incorporators: Charles F. Brozier, William F. Findley, and August Brozier.

C. J. Goodyear has been elected commissioner of the Pittsburgh Coal Producers' Association, succeeding Richard W. Gardiner, who resigned last June. Mr. Goodyear since that time had been acting commissioner. The newly elected official has been associated with the organization for more than four years and for three and a half years was the association's traffic manager. He was identified with the Pittsburgh & Lake Erie R.R. in various capacities for 16 years and for two years was connected with the Ore & Coal Exchange at Cleveland. He left the Cleveland organization to accept the traffic manager position with the coal producers' organization.

The Pittsburgh Coal Washer Co. is erecting a modern steel tippie with a capacity of 300 tons of coal per hour at the old Sample Run mine of the Clearfield Bituminous Coal Corporation. The headhouse is being erected on the site of an old slate dump, necessitating excavation to solid rock. The equipment to be installed includes shaker screens, a picking table and a loading boom. A rock disposal plant also is under construction.

Fire recently destroyed fourteen houses in the mining town of Arden, about two miles north of Washington. Dynamite was used to check the progress of the fire, seven houses being destroyed by that method. The houses destroyed were owned by the Meadow Lands Coal Co., of which James Cock is superintendent. The loss will aggregate about \$35,000.

The **Cosgrove-Meehan Coal Co.** has purchased the stock of the Harco Coal Co., the merger being effective as of April 1. The capital stock of the Harco company is \$500,000, while that of the purchasing company is \$3,000,000. Payment will be made in stock of the Cosgrove company at the rate of \$15,000 annually at a price not to exceed \$105 per share. This preference stock is a 7 per cent issue, dividends being cumulative and payable quarterly. By the terms of the agreement the Harco company will surrender its charter.

Sealed Proposals will be opened by the Superintendent of Lighthouses, Philadelphia, 2 p.m., May 20, 1924, for **anthracite and bituminous coal**, gasoline, acetylene and acetone for fiscal year 1925. Information upon application.

The annual report of the **Jefferson & Clearfield Coal & Iron Co.** for 1923 shows gross earnings of \$3,989,840; expenses and ordinary taxes, \$3,253,602; depreciation, depletion, interest and federal taxes, \$324,063; profit, \$412,175; dividends, \$4,695,000; deficit, \$4,282,825. Profit and loss surplus on Dec. 31, 1923, totaled \$1,584,729.

A new mine is being opened up by the **Hale Coal Co.** at Phillipsburg. Two shafts have been sunk to the Miller seam. Erection of a steel tippie has started. Its capacity will be 250 tons per hour, hoisted in self-dumping cages. Sundry equipment includes weigh baskets, shaker screens, a picking table and a loading boom, and the necessary conveyors.

WASHINGTON

A new effort is to be made this summer to operate the old **Cherry Coal Co.** mine, four miles west of Castle Rock. H. Simon and N. Anches, both of Seattle, have taken over the property and will make the attempt. They hope eventually to have the mine connected by spur to the line of the Longview, Portland & Northern Ry.

E. P. Lucas, of Bellingham, head of the **Bellingham Coal Mines**, recently announced that his company is **rehabilitating its property**. A new 18-per cent slope is being driven to increase the output of the operation. Heavy steel is to be laid on the slope. A rotary dump has been ordered but some other new equipment will be necessary both top and bottom.

WEST VIRGINIA

Since operations were begun in 1883 there has been produced in Pocahontas territory a total of 283,558,779 gross tons of coal, according to W. E. E. Koepfer, secretary of the Pocahontas Operators Association. A chart he has prepared also discloses that the year of largest production was 1916, when the output was 16,161,782 gross tons. Since the Pocahontas field was opened a total of 35,753,191 gross tons of coke has been shipped. Coke production in the Pocahontas region has been comparatively small in the last three years, the output for 1923 being 136,136 tons, as compared with only 80,900 tons the year before.

The **Wilbur Fuel Co.**, D. J. Carter, president, has purchased the **Vulcan Coal Co.** and the **Eastern Utilities Coal Co.**, with lands and mining plants for about \$1,000,000 and will undertake extensive additional developments. Its purchase includes 1,198 acres in fee, 468 acres with a mining town of 115 houses, mining machinery, etc., producing the Red Stone vein coal.

Lee J. Sandridge, general manager of the **Meriden Smokeless Coal Co.**, with headquarters at Philippi, has been undergoing treatment at the Davis Memorial Hospital, at Elkins.

W. Kirby Schaefer, assistant labor commissioner of the Northern West Virginia Coal Operators Association, has resigned, his resignation taking effect early in April.

It is shown in statistics compiled by the **Winding Gulf Operators Association** of West Virginia that a total of **35,778,101 tons of smokeless coal** was produced during the calendar year ending Dec. 31, 1923, which was not far short of the maximum reached in 1916, when 36,000,000 tons was produced. The increased tonnage in 1923 over 1922 amounts to 2,009,335 tons, states the **Winding Gulf report**. The Pocahontas district, producing a little over sixteen million tons, was still short of 1922 production by more than 500,000 tons. The **Winding Gulf district** in 1923 also was short approximately 57,000 tons of 1922 production and the **Tug River field** was short some 32,000 tons as compared with the previous year. To the New River field must go the great increase in tonnage in 1923, having produced over eight million tons, an increase over 1922 of 2,634,049 tons. As

usual, the bulk of the smokeless tonnage came from the mines on the **Norfolk & Western Ry.** The **Pocahontas** and **Tug River** fields produced over one-half the year's output. Over five and a half million tons of the year's production was "captive coal," or coal consumed by those interests producing it. Of this tonnage, the **United States Steel Corporation** consumed slightly over four million tons, all produced by its mines in the Pocahontas district. The year 1923 registered a high-water mark in coal tonnage hauled by the three railroads serving the smokeless fields of West Virginia, the **Chesapeake & Ohio** leading with nearly 33,000,000 tons, followed by the **Norfolk & Western** with nearly 31,000,000 tons. The **Virginian** experienced its largest year, with nearly 8,000,000 tons to its credit.

The **Hunter Crucible Steel Co.**, of Cleveland, has consummated negotiations for the purchase of 4,064 acres of coal land and three mines in Upshur, Webster and Nicholas Counties, the deal involving something like \$1,800,000. Included in the purchase were the **Excello** mine of the **Hesper Coal & Coke Co.** and 764 acres of **Kitanning** coal land; **Pittsburgh** mines Nos. 1 and 2 of the **Philmont Coal Co.**, together with 600 acres of **Pittsburgh** in Upshur County, near **Buckhannon**, and a tract of 2,700 acres of coal in the **Kanawha** series, so far undeveloped, in **Nicholas** and **Webster** Counties, owned by the **Stanfield Coal Co.** The same people are interested in all three of the selling companies, **L. O. Knipp**, of Philadelphia, being president, and **George H. Grone**, of Philadelphia, secretary and treasurer. The mines purchased have an aggregate production of 45 cars of coal per day. This, it is proposed to increase to about 2,500 tons a day through additional openings and the installation of additional equipment. The output of the mines acquired and to be opened will be used by the steel company to supply its mills at **Pittsburgh** and **Cleveland** with fuel.

The **Killarney Smokeless Coal Co.**, chartered under the laws of Virginia, has been authorized to transact business in West Virginia.

ALASKA

The **Evan Jones Coal Co.**, operating in the **Matanuska** field of Alaska, is about to install a complete washery, according to "Jack" Collins, of Anchorage, Alaska, one of the principal stockholders. **Oscar Anderson** of Anchorage, president of the company, has just returned from the States where he went to purchase a steamer and make other arrangements for an attempt at marketing coal from the **Evan Jones** mine in the **Alaskan** coast country.

CANADA

By a vote of 24 to 4 the **Nova Scotia** Legislature has passed a resolution stating that "in any readjustment of the federal tariff to be considered by the federal Parliament at its present session, this House is of the opinion that proper consideration be given. (a) To so increase the tariff on **American slack coal** as to preclude it from entering into this country in unfair competition with slack coal from the **Nova Scotia** mines; (b) to so readjust the tariff that this slack coal will not be sold as run-of-mine coal without paying the customs duty which run-of-mine coal is subject to; (c) to place some duty upon the importation of **American coke** with a view to encouraging the manufacture of **Nova Scotia** coal into coke for the purpose of supplying the **Quebec** and **Ontario** markets, and as a substitute for **anthracite**."

Roy M. Wolvin, president of the **British Empire Steel Corporation**, speaking at a recent luncheon, declared that his corporation would continue to pay the coal miners of **Nova Scotia** the 1924 rate of pay agreed upon at **Montreal** between representatives of the miners and the company. He said that large quantities of **American coal** were being used in **Quebec**, and that it was the intention of his corporation to displace some of that this year. Some sales will have to be made at much less than the average cost of coal delivered, but "we will do our part."

The **Clear Mountain Coal Co.**, which has been developing a property in the **Lillooet** mining division of **British Columbia**, has sunk two prospecting shafts through a seam of coal ranging from 8 to 10 ft. thick and at a depth of about 30 ft. below the surface. The company announces that it will erect coal bunkers at **Pavilion**, on the **Pacific Great Eastern Ry.**, and will convey the coal from the mine to railway in five-ton motor trucks. The general

manager expects to be able to maintain an output of 200 tons per day, which, it is thought, easily will be absorbed by towns situated on the railway.

Hillcrest Collieries, Ltd., reports net profits for 1923 at \$117,958, as compared with \$91,960 in the preceding year. Miscellaneous revenue amounted to \$37,704, which brought the total net revenue to \$155,662, as compared with \$126,730 in 1922. After deductions of bond interest at \$16,250 and preferred dividends \$49,399, there remained \$90,013 applicable to the common stock, which was equal to 9 per cent and compares with \$61,081 in the previous year. Surplus for the year after deduction of \$15,000 for contingent reserve was shown at \$15,013, which, added to the previous balance of \$269,174, brings the total profit and loss balance to \$284,187. An increase of about \$100,000 is shown in the net working capital of the company, which is placed at \$580,877.

A new 7-ft. seam of semi-anthracite recently was uncovered at **Coal Canyon**, in the **Peace River** region. So far, this is the largest seam of coal that has been found in this field. The principal owners of coal areas in this district are negotiating with the **Canadian Pacific Ry.** for the extension of the **Edmonton, Dunvegan & British Columbia** branch from **Spirit River**, the present end of the line, to the property. The distance is only 125 miles through a country offering few engineering difficulties, and the construction of the line would make available what undoubtedly is the highest grade of coal so far discovered in western Canada.

William Wilson has been appointed manager of the **South Wellington** mine of the **Canadian Collieries (D) Ltd.**

Robert Laird, who was manager at **No. 1 Mine**, **Western Fuel Corporation** of Canada, now is the manager of the **Wakesiah Mine** of the same corporation. His place at **No. 1 Mine** has been taken by **Arthur Newberry**.

According to a recent statement the supposed hard-coal area at **Sudbury** is to be definitely tested this year by **United States** interests, under whose auspices leasing for drilling tests was now under way.

The **Okonite Co.** of **Passaic**, manufacturers of "Okonite" insulated wires and cables, splicing tapes, etc., recently appointed the **Engineering Materials, Ltd.**, **McGill Building**, **Montreal**, **P. C.**, as their **Canadian** representatives.

The new 5 ft. seam opened some weeks ago by the **Princeton Coal & Land Co.** is developing well and is adding appreciably to the company's output.

Industrial Notes

H. H. Valiquet, for the past eighteen years chief engineer of the **B. F. Sturtevant Co.** (Chicago division), has joined the organization of the **Kirk & Blum Mfg. Co.**, **Cincinnati**, Ohio, as chief engineer, specializing in the designing of dust-collecting and pneumatic conveying systems, drying, heating, ventilating, cooling and fume removal systems, air-conditioning systems including humidifying, dehumidifying, and automatic temperature- and humidity-control systems.

Within the last few weeks the **Spring Canyon Coal Co.**, of **Storrs**, **Utah**, placed a contract with the **Link-Belt Co.**, of **Chicago**, for a large capacity tippie. This tippie will include an extensive dry cleaning plant for fine sizes. Erection and construction work on this tippie will start as soon as conditions permit.

The **Haridan East Brady Coal Co.**, **Logansport**, Pa., is installing complete shaker screen equipment furnished by the **Fairmington Mining Machinery Co.**, **Fairmont**, W. Va.

The **Crozer Coal & Coke Co.**, of **Elkhorn**, has contracted with the **Roberts & Schaefer Co.** for a new steel tippie and screening bins. The tippie will be complete with the latest improved **Marcus** screen, shaker loading booms and latest devices for re-screening fine sizes of coal. This will be one of the most modern tipples in the **Pocahontas** field.

The **Sterling Anthracite Coal Co.**, at **Clarksville**, Ark., is equipping its mines with new and up-to-date handling and preparation machinery, including automatic weighing pan, feeder, breaker, shaker screens, picking tables, loading booms, boilers and engines. The **United Iron Works, Inc.**, of **Kansas City**, Mo., is doing the engineering work, furnishing and installing the equipment.

Traffic News

Indiana Rate Cut May Be Postponed Again

Following a preliminary hearing on a petition of twenty-one railroads in Indiana to set aside a recent order of the Public Service Commission that rearranged and reduced intrastate coal rates, an agreement was reached April 6 in Superior Court, Indianapolis, to ask the commission to defer the date of taking effect until June 1. May 19 was set as the date to hear evidence on the petition. The original order of the commission, that was written by Oscar Ratts, of the commission, provided that the rates would go into effect April 1. The date later was changed to May 1. Judge Hay said that in case the commission did not extend the time limit of the order to June 1, as requested, a temporary injunction would be granted.

In the petition asking that an injunction be granted setting aside the order of the commission, the railroads allege that the order will decrease their revenue more than \$1,000,000 a year. The order provides for a decrease of about 10 per cent in coal rates to dealers and large consumers. The rates on some roads, however, are slightly increased.

Hearing in Mine-Rating Case Postponed by I.C.C.

Hearings in the mine-rating case, set for April 23, will be postponed until some future date, according to an announcement by the Interstate Commerce Commission. Owing to those most vitally interested in this case being involved in the Lake Cargo Coal Case, which is set for hearing April 22, it was felt by the majority of those interested that justice could not be done the mine-rating case at this time. It is probable that the hearing will be set for some time in June.

Illinois Central Builds Branch

The Illinois Central R.R. is contemplating construction of a branch of several miles to connect the Eldorado-St. Louis branch with the new proposed Edgewood-Metropolis cutoff. The new branch will shorten the route of the output of the Williamson and Franklin county mines. Right of way has been procured for this new branch and work probably will begin at an early date.

Obituary

George W. Hill, Western sales manager of the Chesapeake & Virginian Coal Co. and member of the Executive Committee of the American Wholesale Coal Association, died April 10 at Asheville, N. C., where he had gone to regain his health following an attack of pneumonia last winter. His death was unexpected.

Earl A. Henry, chief of the West Virginia Department of Mines under former Governor Henry D. Hatfield and general superintendent of the Liverpool Salt & Coal Co., of Hartford, W. Va., died suddenly on March 31 while at work in the mine of the company. Heart failure is said to have been the cause of his

death. Before becoming chief of the department of mines Mr. Henry served for a number of years as a district mine inspector and also had been a deputy sheriff of Mason County. Mr. Henry is survived by his widow, his father, Darius Henry; a brother and two sons.

H. D. Megary, managing director of the Consolidated Pneumatic Tool Co., London, England, died suddenly March 20. Mr. Megary was born in Philadelphia, April 21, 1888, and was graduated from the University of Pennsylvania in 1909. Following his graduation he became affiliated with the Bethlehem Steel Co., remaining with that company until June, 1918, when he became connected with the Chicago Pneumatic Tool Co. as assistant to the president, later being made secretary of the company. In 1921 he was transferred to London to assume the duties of managing director of the English company. He also was director of European sales.

Charles Tedrow, of Nelsonville, Ohio, who had been in charge of the land department of the New York Coal Co. for a number of years, died recently at the age of 67 years. The funeral was held March 20, and was attended by officers and department managers of the New York Coal Co.

D. D. Christie, died in Guelph, Ont., recently, at the age of 85 years. The late Mr. Christie was president of the Winnipeg Fuel & Supply Co., Winnipeg, Man., and also was a director of the Drumheller mines, in Alberta.

Coming Meetings

American Welding Society. Annual meeting, April 22-24, Engineering Societies Building, 33 West 39th St., New York City. Secretary, W. M. Kelly, 33 West 39th St., New York City.

Chamber of Commerce of the United States. Twelfth annual meeting at Cleveland, Ohio, May 6-8. Secretary, D. A. Skinner, Mills Bldg., Washington, D. C.

National Exposition of Coal Mining Equipment and Machinery of the American Mining Congress, May 12-17, Cincinnati, in conjunction with the annual meeting of the National Coal Association.

West Virginia Coal Association. Annual meeting May 13-17, Cincinnati, Ohio. Secretary, W. H. Cunningham, First National Bank Building, Huntington, W. Va.

National Coal Association. Annual meeting, May 14-16, Cincinnati, Ohio. Executive Secretary, H. L. Gandy, Southern Building, Washington, D. C.

Retail Coal Dealers Association of Texas. Nineteenth annual convention, May 20 and 21, Vernon, Texas. Secretary, C. R. Goldman, Dallas, Texas.

Pennsylvania Retail Coal Merchants Association. Twentieth annual meeting and exposition, Commercial Museum, 34th and Spruce Sts., Philadelphia, Pa., May 22-23. Secretary, W. M. Bertolet, Reading, Pa.

International Railway Fuel Association. Sixteenth annual convention, May 26-29, Chicago, Ill. Secretary-Treasurer, J. B. Hutchinson, 600 Michigan Ave., Chicago, Ill.

The American Society of Mechanical Engineers. Spring meeting May 26-29, Cleveland, Ohio. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

American Wholesale Coal Association. Annual convention, White Sulphur Springs, W. Va., June 3-4. Secretary, G. H. Merryweather, Chicago Temple Bldg., Chicago, Ill.

The National Foreign Trade Convention. June 4-6, Boston, Mass. Secretary, O. K. Davis, 1 Hanover Square, New York City.

National Retail Coal Merchants' Association. Annual meeting, Hotel Virginian, Bluefield, W. Va., June 4-6. Secretary, Walter D. Rogers, Transportation Building, Washington, D. C.

Southwestern Interstate Coal Operators Association. Annual meeting June 10, Kansas City, Mo. General Commissioner, W. L. A. Johnson, Keith & Perry Bldg., Kansas City, Mo.

Illinois & Wisconsin Retail Coal Dealers Association. Annual meeting, June 10-12, Delavan, Wis. Secretary, I. L. Runyan, Great Northern Bldg., Chicago, Ill.

American Society for Testing Materials. Annual meeting, Chalfonte Hotel, Atlantic City, N. J., June 23-27. Secretary, Edgar Marburg, University of Pennsylvania, Philadelphia, Pa.

New Equipment

Totally Inclosed Grinders For Mine Shops

For use in coal-mine shops where it is necessary to contend with more or less fine dust, the Glow Electric Co., of Cincinnati, Ohio, have developed a totally inclosed grinder. The inclosing case of this device completely shuts out any dirt or dust flying from the grinding wheels. Suitable guards are mounted over each of the two grinding

Inclosed Grinding Wheel

This motor-driven outfit is totally inclosed so that no dust or dirt can get into the motor or the bearings. The grinding wheels are shielded by means of guards, thus the dust, and fragments are prevented from flying in a direction where they may cause serious danger to the eyes of the operative.

wheels. The grinders are mounted on pedestals which are designed to give a large clearance with a short spindle extension. The outfit is driven by an electric motor, controlled by means of either a push button or snap switch located so that it may be within easy reach of the operator.

Paint-Spraying Gun

Important improvements have been made by the DeVilbiss Manufacturing Co. of Toledo, Ohio in the gun they have been manufacturing for the purpose of spraying paints and varnishes.

All nozzle parts are self-centering, thus making it impossible for the nozzle to get out of alignment even when parts are interchanged. When the gun is used in a horizontal or vertical position the revolving air cap produces a wide fan spray and when the gun is placed in any intermediate position a round concentrated spray is obtained. It is claimed that this gun produces a truly atomized and uniform spray under all conditions.

Another important feature is that all parts requiring any cleaning can be easily disassembled and can always be

kept in condition ready for operation. The gun-shaped handle is well balanced, and rests easily in the hand. The trigger which regulates the flow of paint operates freely.

In mine service when used around electrical equipment the gun has several points of advantage, for the paint or varnish may be made to flow in and around insulating material which could not be reached with a paint brush. Its use for finishing the work on newly installed switchboards, located adjacent to panels and switching equipment carrying power, will result in greater safety to the operator.

Paint Gun Easily Used and Cleaned

This complete little gun weighs only 10½ oz. and can be used with great ease for spraying paint or varnish on any kind of surface. Its use around electrical equipment will make the work much safer than is possible by any other means.

Track Tie Made in One Piece Easily Attached to Rails

A new steel cross-tie to be known as the Bethlehem mine tie has recently been developed and placed on the market by the Bethlehem Steel Co. This tie succeeds the Cambria mine tie manufactured at the Cambria plant of the company.

The tie has fastenings permitting it to be added to or taken from the track without the rails being disassembled. The stationary and movable fastenings are arranged in such a manner that the tie can be slipped under the rails, brought into position and fastened while the rails remain in place.

Fig. 1—Shows How Easily Tie May Be Installed

No special wedges or tools are required to attach this tie to the rails. The larger size ties have two clips which make the joint more rigid and prolong its life.

The rail is fastened to the tie by turning the rotating clips to their clamping positions, using for that purpose a hammer, axe, or any tool available, as shown in the illustration, a feature of the device being that no special wrench or other equipment is necessary for its use.

These ties are made in three sizes, Nos. 1, 2, and 3. Each end of the latter two types of tie is equipped with two fastenings, doubling the holding power. Only one clip is necessary for the holding of the rail, and should this clip become damaged or worn, the reserve clip may then be brought into use by turning it to the clamping position. This feature has the effect of greatly lengthening the life of the tie.

The rotating clips are made of heavy rolled steel with reinforcing ribs back and front, offering a large section on which to hammer them in and out of position.

The tie is one-piece construction and is complete in itself, requiring no extra wedges, loose parts or special tools. These ties are shipped complete ready to install in bundles of convenient size. One man can easily carry fifteen No. 1 ties or ten No. 2 ties.

Shovel Driven by Ford Engine

A new shovel suitable for light stripping and coal loading has been developed by the Glasgow Engineering Co., 3720 N. Newstead Ave., St. Louis, Mo. The machine consists of a bucket or dipper mounted on a pair of dipper sticks, which are carried on a heavy structural steel framework mounted on a Fordson Tractor. The action of the

Fig. 2—One-Piece Steel Mine Tie

With this tie, track laying is made easy. There are no loose parts to get lost and delay the work. This feature is important in mine service, for the supply room is usually a long way from the working face.

machine is similar to that of a baby shovel, except that it is preferable to back the tractor about 4 ft. from the pile of material to be handled and then run it forward into the pile before hoisting the dipper.

This dipper is raised by a cable which runs back to the main hoisting drum and is made to dig into the ground or crowd into a pile by the action of the hoisting cable looped over a sheave on the upper end of the dipper sticks. The side-swinging motion is controlled through two cables which run from each side of the bull wheel back to two small drums on the main power shaft. The whole machine is heavily built to withstand severe usage.

Power is taken from the main power shaft gear of the tractor and is transmitted through a worm and worm gears to a shaft which carries both the hoisting and the swinging drums. The driving gear, worm, worm gear, and ball bearings, are adaptations of standard Ford parts which make replacement in case of emergency easy. The main hoisting drum is 4 in. diameter and 8 in. long, with high flanges and is controlled by a large expanding clutch and a 10-in. hand brake fitted with standard brake lining.

The dipper is built of ¼-in. plate with a renewable cutting lip ½ in. thick. The back is hinged on top and held at the bottom by a latch.

Shovel Relocated as Easily as Truck

Mounted on a Fordson tractor, this shovel can be used to dig, hoist or shovel. The ¼-yd. dipper is elevated and swung by means of power taken from the main drive shaft of the engine.

Number 17

Why Leave Field to Central Power Companies?

MOST coal companies have been willing to ship coal by rail or by water. Few indeed have sought to send their power to market by wire and none through pipes. Surely the invasions of the power companies should awaken the desire in the minds of mine owners to put their power in such form that the demand would be steady and not fluctuating. The power companies are now going into the coal field, opening new mines and thus stripping the mine owner of a large part of the demand for his product, adding to the number of mines at a time when it is generally acknowledged that there are altogether too many mines for the well-being of anybody.

This would not be so bad if it were not for the fact that the power companies accepted what few consumers want, especially in the Middle West, namely fine coal. The market that is thus lost is the most desirable market of all. Without sale for slack, the coal operator is at his wits' end. Slack nearly always has faced a glutted market. The power companies crush their coal and with a few mines can supply what many mines were required to produce under the old conditions when a mine made not only fine coal but a large percentage of lump.

It is time to wake up, for it is now or never. The choice will not long remain open. Soon the power companies will have enough mines and enough power plants to take care of all requirements and then only distant markets can be supplied with fine coal. The mine owner should think over this matter seriously and get into the power-distributing business before all the opportunities are taken up. He has been thinking of the subject for years, but thinking does not consume fine coal nor does it give a steady market—unless that thinking leads to action.

Telling the World

SOME coal company executives do not care to write for publicity; others will not write, but allow their engineers to contribute to technical papers; while still others will not permit any of their employees to write or even speak for publicity. Strange as it may seem, if it is strange at all, the public and men of the industry invariably have a better opinion of a company that tells what it is doing than one that hides every move; in fact, there is a close relation between employee loyalty to the company and freedom of expression.

When the public knows little or nothing about an industry and realizes that its leaders are adverse to any publicity, it quickly comes to the conclusion that there must be something to hide. Similarly, when an employee is denied the privilege of exchanging ideas

among his associates, he soon resents his company's close-mouthed policy.

Frequently we are astonished with the lack of correlated effort on the part of employees of the same company, and this condition is even more acute among engineers of different coal companies. Some companies and some engineers know very little about what other companies and engineers are doing. This condition does not promote rapid progress and is expensive and backward. Often a mining or engineering problem is solved and re-solved at great expense and even danger by individual companies and engineers which cost might have been entirely avoided had interchange of ideas been more general.

Director Bain, of the U. S. Bureau of Mines, has well said that if the twenty-six principal mining states had tried to establish, each for itself, separate experimental stations, the waste would have been enormous. Almost everything would have had to be tested twenty-six distinct times. The Bureau does the work once and for all.

Five thousand coal companies are each trying methods of saving in cost of mining and of developing better and safer ways of performing mining operations. What a waste if their effort is not correlated! What a loss to them all! This the technical press is endeavoring to save—is actually saving for the country.

The old-fashioned policy of hiding everything should be abandoned. Many engineers have been too silently doing their work and should now add to their training the art of self-expression, if they are to be of greatest value both to their companies and themselves.

Is This the Way at Your Mine?

AT SOME mining plants the electrical equipment is fully abreast with the times. The boilers are stoker-fired, the power house is equipped with modern turbines, the power is distributed at high potential to substations near the face where it is stepped down to mine voltage. Every modern electrical device is installed and the electrical engineers in charge have obtained kilowatt-hour costs comparable with the best.

But—and here comes in the mining engineer and the superintendent—no one has taken care of the bonding. That falls to the man who calls himself a mining man, and he, not caring about the electrical equipment, lets this important matter drift. The power so cheaply made, so efficiently distributed, is wasted in the roadways of the mine. No matter how energetically the electrical engineer may fill the barrel, the mining superintendent can empty it with his open spigot.

He can waste it at bonds, he can squander it over excessive grades, he can destroy the locomotives by his bad tracks, he can overload his machines by dull bits, he can overtax the electric system by carelessness in

distributing his loads over the day. There never was an electrical engineer but could be queered by a mining superintendent who would not co-operate with him.

A few conferences might correct this difficulty, but of the calling of conferences, there is no end. They tend eventually to "drivel," especially if not skilfully led and made a matter of careful study. But they do give hints of saving, at least when first started, and they do bring pressure to bear on those parts of the mechanism that oppose themselves to other parts, to those gears which do not mesh. And then there is turnover in officials. There are new elements to bring into line. There is forgetfulness also and a tendency of men to fall out of line if not continually faced with the necessity for co-ordination. The conference is well worth the time expended on it. Try it.

Furthermore, it might be well to give the electrical engineer authority over the bonding of the tracks on which he must rely to obtain his return, and a sympathetic hearing as to the tracks themselves, for upon them he must run his electrical equipment and as to the bits and the cutters from which he must get results without motor burnouts.

Dangerous, some one will say, this duplication of authority in a mine, but dangerous also, where there is no co-ordination, is division of authority regarding what are truly electrical matters. It is this division of authority that makes conferences essential.

Why Should They Complain?

BY THE provision of Section 28 of the "Jones," or Merchant Marine, Act only freight carried in American vessels is permitted to get the advantage of the railroad rates set for exported merchandise. Section 28 by its own provisions was held in abeyance till the U. S. Shipping Board should notify the Interstate Commerce Commission that American vessels can handle all the freight of any given kind to certain harbors. By the terms of the section the commission is obliged then to declare that Section 28 shall come into operation in regard to those ports.

As foreign ships can under their present wage scales underbid American ships and are doing so, this enforcement of Section 28 will raise the aggregate cost of exporting, for if the merchandise goes in American bottoms it will have to pay American shipping rates, which are higher than foreign, and if it goes in foreign bottoms it will have to pay, at least in many cases, higher railroad freights to American ports.

All this seems likely to cause retaliation from such foreign countries as are greatly interested in shipping, though such discrimination is not new. It already has been practiced by at least one other nation—Germany. However, foreign countries may not be opposed to this discrimination, for it raises export rates and tends to keep American goods from being exported and helps foreign goods to replace American goods, and thus does America, perhaps, more harm than Europe. Even the foreign shipping firms are not much injured, for they can engage more profitably than in European trade than they can today because that trade will be bettered by the exclusion of American goods. By our action we have raised a virtual tariff wall against our merchandize. In so far as any nation consumes our goods that nation finds the prices raised but its own mer-

chants more active. In so much as that nation exports goods—and nations with merchant marines are most greatly interested in the differential treatment—it provides that they will do more business in the Eastern Hemisphere and less Transatlantic business. So the conditions partly, if not entirely, correct themselves.

It is our merchants who, by being shut out of European markets, bear the loss. But certain railroads and seaport towns will share it. The railroads leading to ports where there is now no differential or only a small one will charge under the law no more, or but little more, as the case may be, to foreign ships and so will take traffic from those where the differential is high. Those ports with no or low differential also will gain. Other railroads and ports will lose. Consequently interests in this country will conflict. This matter, which is in a sense a tariff issue, like the tariff will be a matter of local interest. One section of the country and one group of interests will be pitted against another. Which will win is not at present apparent.

This matter might be of interest to the coal industry should there be a British coal strike, which now, however, appears unlikely. But the railroads have decided, after a conference, that we never have had a differential on export coal. True we have a tidewater rate, but it was made for shipments to New England, not for foreign trade. The foreign trade simply availed itself of it.

Consequently, say the railroads, we have never had an export differential, and accordingly it cannot be legislated out of existence by making Section 28 operative. Whether the railroads are correct in that conclusion the Interstate Commerce Commission must decide. If the commission declares that there is an export differential in favor of coal, that decision might hinder the shipment of coal if, owing to a British or other coal strike, there should be a demand for it.

Certainly this arrangement, by excluding American goods from Europe, will help that continent to restore its balances and aid it to pay its debts. European nations, within themselves, have conflicting interests such as are found here. Hence nothing is likely to be done. Several countries, including Holland and Japan, have protested, but protest probably will not avail. The matter will be regarded as an internal matter by the American people. It offends foreign countries, which do not like interference with their merchant marines. This is unfortunate to be sure.

Second thoughts, however, may make these nations less critical as second thoughts are making the American people question the validity of the judgment which caused the enactment of Section 28. It is too early to tell whether the section will stand or fall. This, however, is sure, we can no longer feel our former enmity toward foreign discrimination. We always have had our restrictions against merchandise being carried coastwise in foreign bottoms. Now we have this further restriction, so we no longer are able to wonder at the ship subsidies that foreign nations have been disposed to provide to the disadvantage of the American merchant marine and at the expense of their own national budgets.

THE KENTUCKY COAL "BARRENS" ought to be happy. They have defeated the tonnage tax bill and had no 1923 taxable income worthy of note. Now all they have to do is fight for life.

Control House for Substations

Motor-Generator Sets in Two Substations Operated In Parallel and Controlled from Surface

To Keep Controls from Dust They Are Installed in Colliery Yard—
Two Generators of Unequal Capacity Successfully Worked in Parallel
—Method of Lowering Cables—Use Unarmored Cable in Borehole

BY E. B. WAGNER

Electrical Engineer, Lehigh Valley Coal Co.
Wilkes-Barre, Pa.

AT THE Dorrance Colliery of the Lehigh Valley Coal Co., at Wilkes-Barre, Pa., two substations have been equipped with semi-automatic substation equipment to supply direct-current energy for a typical mine load but in a way somewhat unusual. One of the unusual features is the placing of the greater part of the control equipment in a separate building on the surface, the two motor-generator sets being located about 2,500 ft. from the control house on two separate levels inside the mine. About two-thirds of the mine output comes from the 650-ft. level where one of the machines is located, and the other third from the 1,150-ft. level where the other machine supplies the necessary energy.

The power for this colliery was originally supplied from a 300-kw. generator directly connected to a tandem compound engine and a 175-kw. generator directly connected to a simple engine. Both generators were compound-wound and delivered 250 volts. The former unit has been in service 15 years and the latter 20 years, running from 12 to 18 hours daily. Both units are still in good operating condition.

It might be of interest to note here that these two generators were successfully paralleled, in spite of their widely different design, by connecting the series field of one machine in series with the other. A cast grid rheostat shunt was connected across the terminals of

the field so as to shunt enough current to compensate for the difference in the capacities of the generators.

Owing to the rapid advance of the mining face, some of the inside power feeders had been extended nearly 5,000 ft. This, of course, caused excessive line drop, and a pressure at the locomotives as low as 150 volts was not uncommon.

At the locations selected for the converting substations there was no one who could attend to the stations in connection with his other duties, so it was decided to make the control semi-automatic. That is, the equipment would be started by pushing a button, but further operation would be automatic unless a short circuit on the alternating-current system or some other trouble of a similar nature shut down the machinery. The mine, served by these substations, is exceptionally dry and the air very dusty. For this reason, and to facilitate inspection, as much of the control equipment as possible was placed outside the mine. As finally planned, the only equipment that had to be installed inside the mines was: A 200-hp. alternating-current motor with control for a hoist, formerly driven by a direct-current motor; and two synchronous motor-generator sets with complete direct-current control but only one alternating-current control relay for each unit. All the other equipment for the motor-generator sets was to be installed in the outside control house.

That the power lines and control wires from the outside to the substations might be made as short as possible, the control house was located as directly over the substations as the surface conditions would permit. An 8-in. borehole was drilled to the 1,150-ft., or Red Ash, level and was so located as to cut the 650-ft., or Hillman, level in an opening in the coal. The hole was lined with a 6-in. casing pipe down to the solid rock. Through this hole the distance from the control house to each substation was about 2,500 ft. The station in the 650-ft. level was nearly 1,900 ft. from the place where the borehole cut through the bed.

Power is supplied through an outdoor transformer substation controlling a bank of three 200-kva. transformers. Here the voltage is reduced from 11,000 to 2,300 volts. The secondary wires run in conduit to the incoming line panel of the switchboard which is located in a brick control house erected adjacent to the transformer substation. Fig. 1 shows the general arrangement of the substation and control house and the headpiece the interior of the latter. The disconnecting switches of the incoming line are located well above the 2,300-volt busbars so that when they are opened there is little risk of accidental contact with any live parts. The switchboard panels are located on one side of the room, and the starting and running contactors for the motor-generator sets are along the opposite wall.

The switchboard arrangement is shown in Fig. 3. Starting at left, the panels are as follows: Alternating-current feeder panel (not shown); incoming line panel; control panel of No. 1, or Hillman bed, station; relay panel of No. 1 station; control panel of No. 2, or Red Ash bed, station; and relay panel of No. 2 station. The method of control of the mine substation was made as simple as possible, and, in the sequence of starting, each operation completes the circuit for the next following.

Speed acceleration of the two motor-generator sets is controlled by two timing relays. These may be distinguished readily in Fig. 3 as the small metal-covered devices on panels 3 and 5. They are set by experiment to have a slightly longer time delay than the machine which they control requires to reach synchronous speed. The other round metal-covered relay on the third panel is a delay relay, used after an alternating-current power failure, to delay the starting of No. 1 set until No. 2 is again on the line. The oil circuit breakers on the alternating-current substation feeders are set for about 300-per cent load. These open only in case of unusual trouble.

Protection against overloads is afforded by the direct-current breakers located inside the mines on the control panels of the motor-generator. The four large, round metal covered devices on the sub-bases of the panels shown in Fig. 3, are long-time thermal relays. These relays are not required for the usual mine load. The direct-current distributing system being sufficiently split up by several adequately protected feeders. A one-line diagram of the power system is shown in Fig. 7.

The machines can be started or stopped from three points, namely, the main shaft engine house, the control house and the inside station. The scheme of wiring is the familiar four-way electric-light control. To prevent unexpected starting from any of the other control points, the control buttons in the engine house at the shaft and in the inside stations are provided with normally closed contacts which can be locked in the open position. In the control house, this provision is not necessary, the double-pole double-throw control switch being left open when required.

The alternating-current feeders in the borehole consist of three-conductor 1/0 varnished cambric cables with 5,000-volt insulation and a double weatherproof braid over all. The Lehigh Valley Coal Co. has found

FIG. 1

Substation and Control House

Power is delivered to a bank of transformers located adjacent to the control house. Wires to the inside substations are suspended in the borehole. A wire fence encloses the high-voltage switching equipment and extends around the borehole structure and cable supports.

FIG. 2

Red Ash Bed Substation

Flexible conduit was used in many places. The wires pass through conduits with long-sweep bends. Most of the wiring is concealed and protected against dirt and moisture. Auxiliary relays on the main generator breaker trip out independent feeders before the load reaches a point necessitating the complete shut-down of the direct-current mining equipment.

that this type of cable gives excellent service in boreholes and that it does not need to be protected with lead covering, which would add greatly to its weight and make it more difficult to provide support. Where the tensile strength of the copper conductor is insufficient to support the weight, a steel armor is provided for suspension purposes. In this case the 1/0 conductor was of ample strength to sustain its 650-ft. of length, that being the distance to the first level.

The cable support is shown at the left in Fig. 1 between the frame of the lightning arrester and the fence. This was made of three 6-in. iron pipes 18 ft. long, set in concrete to form an equilateral triangle. The top of each pipe was fitted with a flange upon which was bolted an 8-in. 25-lb. I-beam. Under these beams was clamped one unit of a strain yoke. From each arm of the yoke was suspended two suspension-type insulators and a strain clamp. The cable was opened and each conductor fastened to one of these strain clamps. The yokes equalize the load of the cable upon the three conductors. This method of support has been used for the past seven years with no failures to date. At the 650-ft. level, eye bolts in the roof sustain the strain yokes to which are attached the feeders running to the 1,150-ft. level.

Before preparing to lower the cables, the exact cable lengths were obtained from the drillers' log and sufficient cable was stretched across the colliery yard. The cable was then opened and a strain clamp fastened to each conductor.

Over the top of the hole, on wooden supports, was mounted a 4-ft. diameter sheave wheel with an especially large groove. One end of the cable was started over the sheave, and the clamps on the other end were fastened to a piece of 3-in. wire rope. Fortunately the colliery locomotive track was so located that it could be used for the lowering of the cable.

One end of the wire rope was attached to a 5-ton battery locomotive. Then the cable was lowered down

the borehole by hand until its weight was sufficient to keep it moving, after which it was lowered by the locomotive, until just enough cable projected to fasten the clamps into the insulators of the yoke.

A split wooden clamp, about 15 in. long was clamped around cable and rested on top of the casing pipe. With the clamp in place the wire rope was removed and the strain clamps attached to the insulators, after which the wooden clamp was removed. The cables for the

Fig. 3—View of Remote Control Apparatus For Two Automatic Substations

The apparatus mounted on and behind these panels controls the operation of each motor-generator set located in the mines. From left to right they are: incoming line panel; control panel for No. 1, Hillman bed, station; relay panel of No. 1 station; control panel for No. 2, Red Ash bed, station; and relay panel of No. 2 station.

FIG. 4

Hillman Bed Substation

Both substation rooms are almost alike, each being made of concrete. A 3-ton hand-operated traveling crane is provided for moving any heavy parts of the motor-generator set. The entrance to the room is closed by a wire fence and gate thus the equipment is safe and no adjustments can be tampered with by an authorized person.

lower section of the borehole—between the 650- and 1,150-ft. levels—were installed first, the wire rope attached to the battery locomotive being long enough to reach from the surface to the 650-ft. level.

By this method the five pieces of cable were placed in the borehole with the assistance of only a few men and yet the cable while being lowered was at all times under full control. The station control wires, eight in number, four for each motor-generator set, are standard No. 6 D.B.R.C. stranded wires with 600-volt new code rubber insulation. These are dead-ended on a 6x6-in. wood cross-piece supported on iron brackets from the pipe poles. A telephone cable also forms part of the installation. This support can be seen in Fig. 1, just above the middle rail of the fence.

The interiors of the substation rooms are practically alike, except for the number of direct-current feeders, so that a description of the station on the 650-ft. level will suffice. A view looking toward the entrance is shown in Fig. 4. The room is 30 ft. long, 17 ft. wide and 10 ft. 6 in. high with concrete side walls and floor. A 3-ton hand-operated traveling crane forms a relatively inexpensive part of the equipment and is of great service in handling parts of the motor-generator sets during cleaning, inspection or repair.

Unfortunately these machines are so designed that the frames can not be slid off the base, for the motor and generator frames project below the base plate. The entrance to the station is closed by a double-wire screen gate, which is normally locked, to keep unauthorized persons out of the room. Fig. 5, shows the gate closed. In the vestibule outside the station is a pipe frame on which is mounted a non-automatic oil switch and a small panel. In the center of this panel can be seen the start and stop push buttons and the lockout button on the left.

The three knobs mounted above and below the push buttons are the control switches for each direct-current

automatic breaker in the station. Thus, in case of emergency, any one can cut off any direct-current feeder by opening the proper control switch, or cut off the entire direct-current supply and shut down the machine by opening the oil switch. As all current-carrying parts are enclosed, these operations can be performed with perfect safety.

The automatic equipment in the station is mounted on the two 24x76-in. slate panels shown in Fig. 6. The panel on the left has a direct-current voltmeter with plug and receptacle, so that machine or feeder voltage can be read; a direct-current motor-field ammeter; a direct-current main ammeter; concentric hand wheels for field rheostats and a direct-current contactor on the sub-base. The latter controls the circuit breaker of the direct-current generator.

On the top of the other panel is mounted a direct-current voltage relay, which picks up when the direct-current voltage is 70 per cent of normal; a motor field relay which picks up when normal field current is established; a generator field-building relay which short-circuits a portion of the field rheostat, allowing the generator to build up its voltage quickly when started with the machine at normal operating temperature.

In the second row is a polarity relay, a direct-current relay, which disconnects the station in case the direct-current voltage coming from the other station is higher than the voltage of the generator in this station, and a reverse-power relay. This relay is not really necessary when there is only one set in the station, as the direct-current relay just mentioned makes provision against power reversal. The next row has a contactor for the reverse-power relay and an alternating-current contactor forming an interlock between the alternating- and direct-current control circuits. On the switchboard sub-base is a motor-field contactor.

To the right of the slate panels are the direct-

current feeder controls consisting of reclosing circuit breakers and safety-type disconnecting knife switches. The first breaker is in the generator lead, and its overload trip setting is about 225 per cent of the full load on the generator. The next several breakers control direct-current feeders, the one on the extreme right controlling a tie feeder between the two converting stations.

The oil switch located outside the substation is provided with a shunt trip coil and a circuit-opening switch. The former is energized through machine-bearing thermostats or, in case of field failure, by a motor field relay. The circuit-opening switch opens the main control circuit thus dropping out the running contactor in the control house, making a complete restart necessary. This prevents closing the oil switch with full voltage on the supply leads to the motor.

Each machine was placed as near as possible to the center of load on its particular level and, to take advantage of the diversity factor, a feeder was installed to tie the two direct-current station buses together. The generator breaker was set to trip at a rather high overload, so that it would act only under excessive load. This was done to prevent the high starting current taken by locomotives from opening the breaker too frequently after a complete interruption of direct-current power.

To take further care of this condition, two overload relays were installed in the generator lead each with its auxiliary contact in series with the operating coil of one of the feeder breakers. The overload setting of one relay was about 10 per cent and the other 20 per cent below the setting of the generator breaker. When peaks combine on the main breaker, one overload relay opens its contacts and trips out the feeder breaker to which it is connected. If the load continues to increase, the other relay trips out its feeder. This

usually reduces the station load to a safe value. As the load falls off, one relay and then the other drops and recloses the respective breakers. This arrangement, by preventing the generator breaker opening repeatedly on peak loads, has prevented much lost time.

Figs. 5 and 8, showing the two substations give a better idea of the outside control features, the gates and the arrangement of the direct-current circuit breakers. The light streaks on each device are metal name plates, showing the purpose of each switch or push button. The direct-current feeders are run in conduits placed in the side wall of the room, so that the station is remarkably free from visible wiring. The ammeter in Fig. 2 shows that at the time the picture was taken No. 2 station generator was delivering 300 amp. over the tie feeder to No. 1 station bus.

As the greater part of the total mine load was near No. 1 station it was planned at first to have the generator in No. 1 station flat-compounded and the generator in No. 2 station over-compounded. It was hoped that by this arrangement energy could be supplied to busbars of No. 1 station from No. 2 station; the overcompounding of the one generator being sufficient to make up for the voltage drop through the tie feeder.

A few weeks of operation demonstrated that this would not give the result desired, as a heavy load on No. 2 station when No. 1 station was lightly loaded would raise the potential of the tie feeder, due to compounding of No. 2 station generator, sufficiently to force No. 1 station generator off the bus by the functioning of the reverse-power relay. A heavy demand for power near No. 1 station would then trip the main breaker at No. 2 station.

After experimenting a while it was found that each machine must be given a slightly drooping characteristic, in order to get the desired results from the tie feeder. The reverse-power relay was disconnected from

Fig. 5—Motor-Generator Set Stopped from Ante-Room

The oil switch located outside of the substation may be used to stop the motor-generator set in case of emergency. Each direct-current feeder circuit may be closed or opened by means of the control switches located on the slate panel above the oil switch.

Fig. 6—Instrument and Relay Panels

These two panels are located inside the mine with the motor-generator set. All other starting and control apparatus is located in the outside control house.

Table I—Equipment Driven by Power from Motor-Generator Sets

Twenty-one 8-ton locomotives totaling.....	1,596 hp.
One 13-ton locomotive.....	134 hp.
Two hoists totaling.....	90 hp.
Four pumps totaling.....	65 hp.
One box-car loader.....	15 hp.
One empty-car haul.....	15 hp.
Lighting.....	5 hp.
Total direct-current equipment.....	1,920 hp.

the generator breaker and connected so as to control the tie feeder breaker at No. 1 station. This allowed No. 1 station generator always to be connected to its station bus ready for any power demands that might be made.

After several months operation of the equipment, it was found desirable to have some means of indicating at the control station in the engine house at the shaft when each station was in operation. As there was an

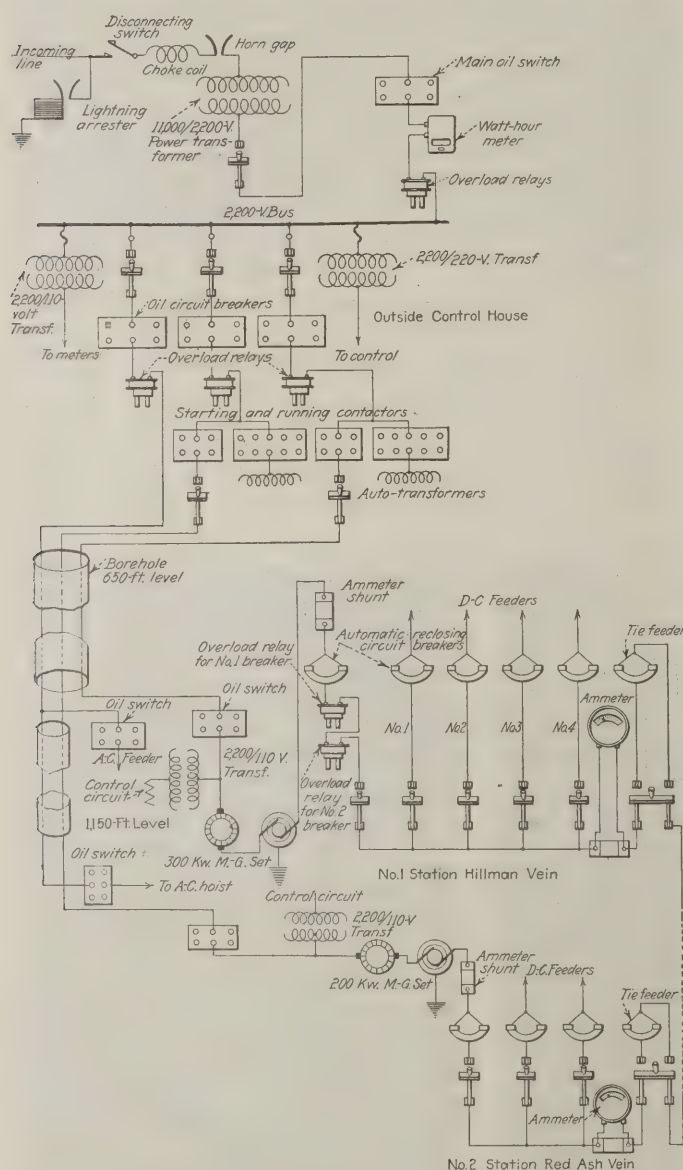

Fig. 7—One-Line Diagram of Power System

The power system divides itself into four parts; the power transformers, control house and two inside substations. Only 2,300-volt energy goes into the control house. There it is distributed to an alternating-current motor-driven hoist and the Hillman and Red Ash bed substations. The direct-current system is split up into many feeders, each controlled by automatic reclosing circuit breakers. A tie feeder connects the two substations and at night one motor-generator set supplies power to all the feeders in both stations.

Fig. 8—Control Buttons Outside of Red Ash Bed Substation

The general view of the substation shows how everything has been arranged to make inspection and repair work as simple and easy as possible. Each direct-current circuit is provided with a disconnecting switch enclosed in a steel cabinet.

extra circuit-closing contact on each running contactor of the motor-generator sets, two wires were run between the control house and the engine house at the shaft and connected to lamps enclosed in red globes. With the closing of either of the two running contactors the respective lamp is lighted, giving the necessary indication.

The equipment in Table I is furnished with direct-current power from the motor-generator sets.

The figures in Table II show that a large diversity factor may be expected when the number of locomotives supplied with energy is relatively large.

The locomotives at this mine are used mainly for gathering and they make relatively short hauls to the main haulage roads. However, many of the chambers pitch steeply, at gradients varying from 8 to 18 per cent. This explains the small number of main-haulage locomotives.

Before the voltage regulation of the two generators had been satisfactorily adjusted, so that a reasonable amount of direct-current power could be interchanged between the two substations over the tie feeder, and before the installation of the direct-current overload relays in the generator lead of No. 1 substation, the monthly 15-minute maximum demand for the entire operation was as high as 634 kw. In addition to the foregoing improvements, automotoneers were installed on most of the locomotives, and some changes were made in the method of handling trips. The maximum demand then dropped to 525 kw. but has since increased gradually to about an average of 575 kw.

The automatic substations have been in service for 18 months. The delays, directly due to failure, have been few and of such short duration as not to interfere with the output of coal. In fact it has been my experience that such minor delays need not be considered when automatic substation equipment is proposed.

Table II—Capacities, Loads and Power Demand of Machinery at Dorrance Colliery

Total capacity of motor generator.....	500 kw.
Connected load per kw. of generator capacity.....	3.84 hp.
Assuming 80 per cent average efficiency of motor-generator set the equivalent connected load to alternating-current side is.....	2,400 hp.
One alternating-current hoist.....	250-hp.
Total alternating-current connected load at mine.....	2,650 hp.
Capacity of transformer bank.....	600 kva.
Connected load per kva. of transformer capacity.....	4.4 hp.
Average monthly power consumption.....	105,000 kw.-hr.
Average monthly maximum 15-minute demand.....	575 kw.
Kilowatt demand per horsepower of connected load.....	0.22 kw.

Turning a Room with Straight-Face Machine

Utah Company Uses Top Cutting Successfully

Cutter Bar Bent to Avoid Loss of Height—Top Cutter Saves Its Cost in Timber, and Coal Lost in Roof Is Compensated in Coal Saved in Drawing Pillars—Suited Only to Thick Coal

BY THOMAS A. STROUP

Mine Superintendent, Utah Fuel Co., Clear Creek, Utah

SINCE 1915, the Utah Fuel Co., has had three straight-face mining machines in constant use at its Clear Creek property. During this time many data on the operation of such machines and on the application of top cutting to coal mines in general have been accumulated.

Wherever the physical conditions encountered are suitable, top cutting is a highly advantageous method of mining because of the ease of operation, the appreciable economy in labor and the great capacity obtained from a single machine. Under unfavorable conditions, however, this method is troublesome and wasteful. Mines adaptable to top cutting are, however, not uncommon, and this mode of mining deserves a much wider application than it now has. For several reasons, the idea of top cutting has always appealed to mining men. When it is used the roof rock is protected by the top coal and is not shattered in shooting. The method promises great economy in the use of timber as well as increased safety in mining. It has always seemed obvious that a coal-cutting machine that remains on the track while in operation would be highly advantageous. Furthermore, a machine with an adjustable height of cutter bar would certainly be of use in cutting shale and bony bands from the coal, thus insuring a clean product. These, in short, are the chief reasons for interest in top cutters.

In general, top-cutting machines have been developed along two separate lines, and at present are of two fairly distinct types. The arcwall machine is representative of one variety. This cuts by a swinging motion of the cutter bar about the axis of the machine.

It consequently makes a cut in the form of a circular segment. The Oldroyd machine, which has been developed more recently, makes a cut of the same general characteristics. It is believed by many engineers that a cut of this nature is tight on the ribs and difficult to shoot. There is unquestionably some foundation for this view, but the difficulties encountered have doubtless been overestimated.

A second type of machine designed to secure a square face in the room or entry being worked and one exactly similar in shape to that produced by an ordinary undercutter has also been developed. This is known as the straightface overcutter and was designed to overcome the objections incident to the circular cut. At the expense of a somewhat more complicated mechanism

Fig. 1—Straight-Face Cutter at Work in a Room

The tendency of the cutterbar to crowd up or down may be seen by contrasting the offsets in the roof. Apparently this tendency can never be entirely avoided.

Article entitled "Use of Overcutting Machines" read at February meeting of Rocky Mountain Coal Mining Institute. Illustrations by courtesy of Goodman Manufacturing Co.

Operating Positions of Straight-Face Machine

Fig. 2—Operation and Clearance of Straight-Face Machine

By utilizing a cam cut in the base plate of the machine the cutter is constrained to excavate a square place instead of one that is semi-circular thus enabling the coal to shear on the lines of cleat.

than that employed in the arcwall, this machine gives a straight cut across the face and one that lends itself admirably to present-day shooting methods.

Top cutters cannot be advantageously introduced into all coal beds. Measures less than 6 ft. thick are little adapted to them, unless the problem encountered is that of cutting out a bone or clay band, and then removing the coal from both above and below it. In ordinary top cutting from 6 to 12 in. of coal must be left in place, in order to avoid cutting into the roof rock, also to provide the necessary cutting angle so that the place will not tend to lose height, as will be explained later. The ideal thickness of a coal bed for the use of an overcutter is 7 ft. or more. With straight-face machines the coal is cut preferably from 6 1/2 to 7 1/2 ft. above the rail. Hard shale bands cannot be removed with these machines, as well as they can with the ordinary shortwall machine, for the driving mechanism and cutter bar form a more rigid unit. The cutter will be deflected into the more readily cut coal.

At Clear Creek, a band of hard dark shale from 1 to 3 in. thick occurs about 18 in. below the top of the 8-ft. bed. This parting is persistent and extends all over the mine. Repeated attempts have been made to cut it out, but all have failed. At low feed the machines have ample power for the work, but the deflection of the cutter bar cannot be controlled. So great is the force of this deflection that in extreme cases the entire machine, weighing 7 tons, has been lifted clear of the rails, or, in the case of downward pressure, the rails have broken under the machine. Pressures of this magnitude may occur in shortwall work also, but they are not serious as the weight of the machine is appreciably less and its movement is virtually unrestricted.

Top cutters must not be expected to remove bands of

impurities that are appreciably harder than the rest of the coal bed. The presence of irregular masses or lenses of hard material also is fatal to the work of the top cutter. For best results, the coal must be uniform in texture, and impurities, if they occur, must lie in regular bands that can be avoided in cutting.

Top cutters create more dust than shortwall machines, for the bugdust must fall further to reach the floor. Application of water to the cutter bar, which is entirely practical with the shortwall machine, is a failure with top cutters. The cutter bar being located above the electrical driving unit, any water that may be applied will find its way to the motors and controllers. Of course, dust on the floor and at the face may be kept wet, but that made by the machine during the cutting process cannot well be controlled. In mines where the dust is particularly flammable, it would be well to avoid the use of top-cutting machines.

For the successful operation of top cutters the coal should part readily from the floor. At the bottom of some coal measures occurs a layer of impurities which may be "frozen" to the rock floor. In shortwall cutting, it is obvious that the cutter bar will work above these impurities. In top cutting, however, they are liable to be lifted from the floor in shooting and have to be sorted out of the coal. If the lower strata, where the impurities or clean coal are "frozen" to the bottom, the shoveling surface is rough and the efficiency of the loaders is greatly reduced.

An ideal bed for the use of a top-cutting machine is one that is free from impurities at the bottom and which breaks free from the footwall, leaving a smooth floor on which to shovel. This is the condition at Clear Creek and it has contributed in on small measure to the success of top cutting.

The character of the roof determines how much timbering is needed and so is also a potent factor in top cutting. As the machine swings horizontally from a fixed center above the track, it requires more room than an undercutting machine. In all cases, it is advisable to keep the timbers at least 21 ft. from the face. A row of props, however, may be set if required 4 ft. from the rail upon either side to within 14 ft. of the face. If the roof breaks up to the face, it will be necessary to break down the top coal and cross timber the place at a sufficient height to clear the machine. One great advantage of top cutting, however, is that a small layer of coal may be left undisturbed to protect the roof. Nevertheless with extremely bad roof this slab of coal in itself is liable to be dangerous. Under such roofs top cutting should be avoided.

Such machines as are used at Clear Creek obtain their straight-face motion from a cam cut into the base plate of the machine, upon which the entire mechanism moves. This renders the method of sumping the machine and withdrawing it from the cut somewhat unusual. In practice, the machine is run up to the face, the cutter bar swung to the corner where cutting is to start, which, at Clear Creek, is the right-hand side of the room. The miner in preparing his place has drilled a sump hole 18 in. deep 3 ft. off the floor and 18 in. to the right of the center line of the place. Into it the sump hook is driven as shown in detail in Fig. 3.

The machine is now started and pulled into the cut by a rope extending from the hook to a drum on the rear of the machine. When the latter has been pulled forward to such a point that the base plate touches the

face of the coal, the live drum is disengaged and the machine blocked in place for making the cut. This blocking is necessary for by it the machine is held in place despite the stresses encountered during cutting. It consists of props or ties placed against the ribs and against the frame or wheels of the machine itself. Even with these precautions, the operator of the cutter must be constantly on the alert to see that the machine is not lifted from the track, or the track pushed to one side by the heavy forces acting upon it. A device for raising and lowering the cutting mechanism either by hand or power is provided to relieve the strain should this happen.

After the sump rope has been cast off the machine makes its cross cut by being simply traversed on the cam by means of a pinion working on a quadrant on the base plate. The path described by the end of the cutter bar is a straight line which may vary in length up to 18 ft., depending on the starting and stopping positions of the machine on the cam. The cutter is withdrawn from its cut by means of a rope and jack pipe using the live drum again as a means of propulsion. This entire cycle of operation can be completed in an 18-ft. place in from ten to fifteen min.

All top cutters require good track. At Clear Creek, 30-lb. rails are standard, these being laid on 5x5-in. pine ties. In the past, however, some 20-lb. rails were used. By careful attention to laying, close spacing of ties and the proper fish-plating of all joints, 20-lb. rails may be successfully used. They are not, however, recommended. The track must be extended clear up to the face for each cut. For this purpose, pieces of rails from 6 to 7 ft. long are provided.

The track must be blocked up till it is approximately level and must, of course, be brought to gage and cross-leveled. It is also necessary to brace it against the ribs upon either side, so as to prevent the machine from pushing it over while cutting. The work is continuously advanced by laying the short pieces of rail above mentioned, but whenever a sufficient distance has been gained, these short pieces are lifted and a full length of rail laid. At the present time, the miners at Clear Creek are laying their own track. This work requires about one hour per cut, or per day.

When the top cutters were first introduced into these mines much difficulty was experienced for the places tended to lose height. An exhaustive inquiry into the cause and possible remedy for this condition was made, as it was understood that this was a common fault with machines of this kind and a detriment to their continued operation. As little assistance could be obtained from outside sources, the entire problem had to be solved locally.

It became evident from the outset that the roof would consist of a series of offsets and angle cuts, the front end of each cut being higher than the rear end. The

Fig. 3—Room-Drilling and Sump-Hook Details

Three shot holes which lack 6 in. of being as deep as the top cut and one sump hole usually about 18 in. deep are all the holes it is necessary to drill in the room face.

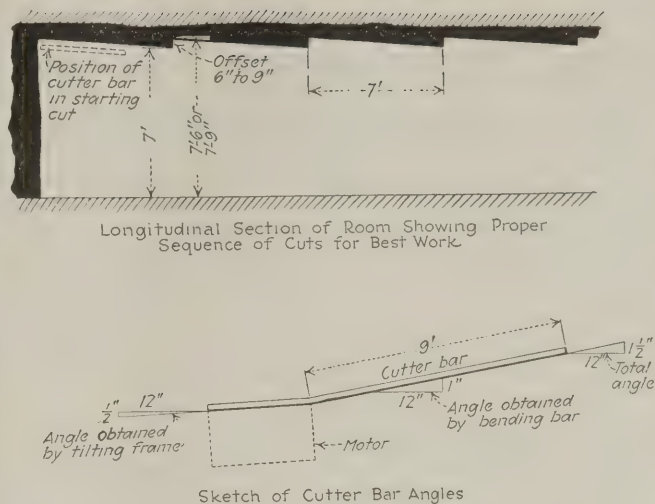

Fig. 4—Angle and Cut Made by Cutter Bar

Although the bar was tilted upward at an angle equal to $\frac{1}{2}$ in. per foot, this was not enough and it was given a bend of $\frac{1}{2}$ in. per foot. This gives the bar a total upward inclination of $1\frac{1}{2}$ in. and to the portion of the bar engaged in cutting a rise of $10\frac{1}{2}$ in.

builders of the machine had provided a slight adjustment on the front trucks by means of which the entire front of the machine could be raised until the nose of the cutter bar was about 6 in. above the horizontal, the bar thus making an angle with the track. It was soon found that this was far too slight an inclination and after much experimenting with methods of blocking up the front end of the machine, it was decided to try bending the cutter bar itself. This was done and it solved the problem completely, the coal now being cut continuously without recourse to brushing, which was a common and troublesome expedient for overcoming lost height before the bar was bent.

In practice, the cutter bars are heated and bent just forward at the clamp that binds them to the motor housing. The extending portion of the bar thus makes an angle with the portion clamped to the frame, this inclination being 1 in. per ft. The free portion of the bar is 9 ft. long, in order to obtain a cut 7 ft. in depth. Through the adjustment on the frame of the machine already mentioned an inclination to the horizontal of $\frac{1}{2}$ in. to the foot can be obtained, so that the total inclination of the bar is $1\frac{1}{2}$ in. per ft. This gives an offset or inclination of $10\frac{1}{2}$ in. in a cut 7 ft. deep. In making the cut, however, the bar almost invariably bears downward at the point, and the usual offset in the roof is from 6 to 9 in.

Fig. 4 shows in detail the roof offsets and angles made, as well as the alterations in the cutter bar found necessary to bring the machine to its highest efficiency. No difficulty has been encountered in making the chain follow the slight vertical bend in the cutter bar. Everything considered, therefore, the problem of losing height has been satisfactorily solved.

The cutter bars on these machines are built in a somewhat peculiar manner. A heavy T-rail is planed down to the width of the chain and hard steel guides riveted to it. Some trouble has been experienced from the breaking of these rails. It has been found feasible, however, to torch-weld the broken rail so that the expense is not as great as in the past. For the three machines employed at these mines, two spare cutter bars are kept ready in case of a breakdown of this character, or in case a bar is bent down to such an extent as would cause a probable loss of height. These

bars are bent to the proper angle before being sent into the mine. Two men can change one in about two hours.

The crew necessary to operate one of these machines consists of two men; an operator who controls all machine movements and a helper who handles the sump rope, brake, cable and makes himself generally useful. At these mines the men work on a tonnage basis, the rate being 10.3c. and the division of proceeds being 55 per cent to the runner and 45 per cent to the helper. As many as fifteen to sixteen places may be cut per shift if little traveling is involved and no operating trouble arises. From nine to eleven places, however, ordinarily are cut in one shift.

The average of power consumption is 43 hp. for a 6 ft. 9 in. cut with sharp bits. Readings for individual cuts have run as low as 35 hp. and as high as 48 hp. Power consumption should not vary appreciably from mine to mine.

Two men can change a set of bits in 15 min. The bits used at Clear Creek are of ordinary carbon steel tempered in black oil. Seldom will a set of bits (64 in number on the present machine) cut more than two places, and one place to a set is more common. It thus may be seen that the time consumed in changing bits approximates that employed in actually cutting the coal.

The possibility of using alloyed and self-hardening steel bits is deserving of study, as the wastes existing at present are obvious to anyone. The fact that the most glaring inefficiencies are covered by the contract wage does not decrease their seriousness. In fact the most grievous inefficiencies and the most costly ones encountered in present-day coal mining are found in contract work and are not the result of official organization or of day labor. One of the coal industry's most pressing problems is to correct these evils and to obtain cheaper coal as its portion of the benefits arising from their correction.

As has been mentioned, the saving in timber is an appreciable item in favor of top-cutting machines. In coal 7 to 8 ft. high with only a fairly good roof, such as that at Clear Creek, this saving is appreciable. It can only be estimated, of course, but it is believed that the original cost of the machine is saved every three years in timber alone, without any consideration being given to the labor required in setting it. The system of timbering employed in a top-cut room is shown in

Fig. 5—Clearances and Method of Timbering

The machine being long, it is necessary to give the room mouth an easy curvature, the rail being laid on a 22-ft. radius. As the machine must cut with a sweep, the nearest inside prop must be 21 ft. from the face.

Fig. 6—What a Straight-Face Machine Cut Looks Like When Shot

From this picture the large percentage of lump attained by the use of the overcutter may be readily imagined from the size of the pieces shown in the illustration. Of course such pieces as these must be broken down with a pick before they can be loaded.

Fig. 5. Only props are used and many of these are ultimately recovered.

Even a small layer of top coal constitutes an effective bridge between the ribs of the place. This largely prevents the ribs from scaling and keeps the pillars in good shape while they are being drawn. Obviously when top coal is thin, none of it is recovered, but the increased recovery from the pillars usually far more than counterbalances this loss. Pillars in top-cutting mines always are drawn with less loss of coal and less expenditure for timbers than in those where shortwall machines are being used. In some measures this is because where top cutters are used the roof is not affected by shooting. It largely results also from the leaving of a coal bridge between the ribs.

The maintenance of top-cutting machines is relatively costly. The average cost at Clear Creek during the past three years has been 9.1c. per ton, exclusive of bits, which cost 1.8c. for replacement and for the labor of sharpening. Oil and grease cost 0.22c. per ton.

Top cutters present also certain advantages in pillar drawing where the end-cutting system is in use. The track can be laid close to the face, the clearance essential for the shortwall machine being unnecessary. The first row of timbers can be set close to the track. The roof break can thus be maintained closer to the face and greater safety and efficiency in operation secured. This method is being tried at Clear Creek, but it is as yet too early to publish details of actual operation.

The future of the top cutter is by no means certain. The introduction of loading machines will change cutting practice greatly. Under present circumstances, and probably in most machine mining, the top cutter should be preferred wherever physical conditions favor its use. For slabbing longwall faces in high coal and in end-cutting pillars this machine has certain advantages. But the perfection of loading machines and the consequent demand for large tonnage per place will probably lead to the development of super-cutters of the shortwall type. It seems possible to assume that cuts up to a depth of 12 ft. can be successfully made and shot, cuts 9 ft. deep having been repeatedly made and brought down without difficulty. That such long cutter bars, however, will be practical on top-cutting machines is open to doubt and beyond question the entire future of cutting is inseparably bound up with the future of machine loading.

Anti-Friction Bearings Lower Transportation Costs from Face to Railroad Car

Need Only One-Fourth as Many Applications of Lubricant as Plain Bearings and Have Nearly Twice as Long a Life—Lubrication Cost Reduced by Two-Thirds—Save Power and Equipment

BY FRANK H. KNEELAND
Associate Editor, *Coal Age*
New York City

WHEN the cave man, attempting to move a load greater than he could lift, became weary of dragging it over the ground and tried the expedient of placing lengths of logs transversely under it and thus rolling it along, he learned an important lesson, namely, that the co-efficient of rolling friction is not nearly as great as that of sliding friction. Of course the primitive individual making this discovery did not realize what he had discovered. Of coefficients of all kinds he knew nothing and probably cared less. What interested him and what he remembered and taught his progeny was that any weight can be moved with far less effort when placed on rollers than when dragged over the ground.

Down through the ages this discovery of the cave man has been utilized. For permanent work, that is, for installation upon vehicles, a wheel turning on an axle fastened to the body of the device to be moved soon took the place of the crude roller. This combined both rolling and sliding friction—rolling on the ground and sliding on the axle. As, however, the area of sliding friction was small and susceptible to lubrication, the shortcomings of rubbing friction were largely overcome. Even the ponderous creaking ox cart still used largely in tropical America and elsewhere is a vast improvement over the drag or stoneboat.

BICYCLE DEVELOPS ANTI-FRICTION BEARING

Unquestionably the wheel, whether turning upon or fastened to an axle, which itself turns in a bearing, has been responsible for much of the progress man has made thus far on the road of civilization. It has remained for comparatively recent times, however, to perfect a device whereby the sliding friction of the wheel upon the axle-tree, or of the axle within its bearing or journal, is replaced with rolling friction. Here rollers or balls are inserted between the inner surface of the moving wheel hub and the stationary axle, or between the revolving shaft and its stationary bearing. This arrangement entirely obviates sliding friction, and journals that accomplish this result regardless of their size, kind or type are known and designated under the general name of anti-friction bearings.

Generally speaking, anti-friction bearings are of two types, namely, roller and ball bearings. Both have been used extensively in industrial work and have become familiar to everyone, particularly since the invention of the bicycle and the later development of the automobile. In recent years these bearings have been applied freely in mine transportation. As the roller was probably known and used in industry long before the ball, the bearings employing this element will be considered first.

Because of its shape a right cylinder will roll without slippage only in a direction at right angles to its axis.

Any end movement of the roller is resisted by sliding friction, but its side movement is resisted only by rolling friction.

In its simplest form a roller bearing consists, as in prehistoric times, of a roller, the surface over which it operates and the body resting upon it. In this case the supporting surface, if straight, forms a raceway of infinite radius, whereas the weight carried, provided it be a beam or other object presenting a plane surface, corresponds to the shaft of a modern bearing, also having an infinite radius.

Industrially the roller bearing of the simplest type is composed of a raceway within a wheel if the shaft is stationary, or within a pillow block or bearing if the shaft revolves, together with a sufficient number of rollers to prevent contact between shaft and bearing or between shaft and wheel as the case may be. The harder and smoother all of these parts are made the less will be the resistance offered to rotation.

No matter how carefully and accurately the various parts making up such a bearing as has just been described may be machined, hardened and ground, dirt must be excluded and the rollers held in their proper positions if maximum efficiency is to be attained. Without these provisions such a bearing is difficult to handle, the rollers have a marked tendency to slip out of place and must be put in position one at a time. Furthermore, being put into place individually with nothing to hold them apart they grind against each other, this action being aggravated by any slight differences in diameter which rollers, be they ground ever so carefully, are nevertheless certain to possess.

Fig 1—Cage with Rollers and Race

Solid rollers ground to size are provided with a gudgeon on either end. These gudgeons fit loosely into holes in the end rings which are held apart by four spacers or spacing rods. The race is a strap of steel bent to proper diameter, hardened and ground inside. The V-shaped joint makes the operation of the rollers easy and smooth.

As is well known, dirt in any bearing rapidly destroys it. This is particularly true of those anti-friction types where efficiency depends largely upon nicety of adjustment. Thus in the type of bearing just described dirt entering the raceway from the end or elsewhere, impedes the free rotation of the rollers, and finding its way between these members and either the shaft or raceway, is crushed or ground between these parts just as ore or shale is ground in a Chilean mill. In time such particles uniting with the oil used for journal lubrication forms an abrasive mud, which, accumulating as time goes on, gradually fills the entire space between the rollers.

On the other hand, if the particles of foreign matter entering a bearing of this kind are sufficiently hard to resist crushing, they become embedded in the steel of the bearing and then not only destroy the smooth surface of the parts but exert an abrasive action exactly analogous to that of a diamond truer on an emery wheel. Although this action is possibly slight for each individual particle, its effect on the aggregate wear and resistance is important.

As a rule the actions spoken of above, abrasion and gumming, take place simultaneously. Sometimes the gumming action becomes so pronounced and the bearings become so "stogged" or clogged with mud that the rollers cease to revolve. When such bearings have operated for a comparatively short time measurements of the rollers as well as of the shafts will show noticeable wear. In extreme instances each roller will become so worn that its cross-section almost resembles a crescent.

FUNCTION WELL ONLY WHEN DIRT IS EXCLUDED

Rollers or balls that do not roll are worse than useless, as they defeat the very object they are designed to accomplish. Consequently, dirt and all other matter except lubricant must be excluded from all anti-friction bearings if they are to function correctly and retain their efficiency for any length of time. Dirt is excluded usually by a felt washer. That this means is effective is evidenced by its almost universal use in the anti-friction bearings of automobiles and other road vehicles which always are subjected to the worst kind of fine abrasive dust.

In order to obtain the best results from a roller bearing, the rollers should be spaced equally around the shaft. This is accomplished by means of a cage. This

Fig. 2—Another Well-Known Type of Roller Bearing

Here the rollers are wound from high-grade alloy steel. This construction gives greater flexibility and assures larger grease-carrying capacity than is obtained with solid rollers. Winding them alternately right- and left-hand assures proper distribution of lubricant and uniform wear.

inclosure may vary greatly in its details of construction, but all varieties nevertheless follow the same general plan. The one shown in the accompanying illustration, Fig. 1, consists of two end pieces with suitable spacing rods extending between them. The end plates are rings with the internal diameter somewhat greater than the diameter of the shaft, their radial width being less than the diameter of the rollers. The spacers or standards are passed through holes drilled through the end plates and their ends are riveted down flush. The rollers, which are hardened and ground, are provided with projections, or gudgeons, on each end. These fit loosely into holes in the end pieces. The cage thus built up holds the rollers together as a unit, yet leaves them free to roll between the shaft and raceway.

RACEWAY GIVES EFFICIENT BEARING TO ROLLERS

In order to assure an efficient bearing for the rollers, the raceway, also shown in the illustration, is provided. This consists of a strap, or plate of steel, the ends of which are male and female V-shapes. This is bent to a circular form after which it is hardened and ground. As will be observed in the illustration the edges of the V's stand apart when the raceway is removed from the bearing. Before it can be slipped into place this opening must be sprung together. The V-shape of the opening avoids all possibility of distinct shock as the rollers cross it. A raceway of this kind assures a smooth, even surface upon which the rollers may operate, and may be renewed with ease if necessary.

In some instances the rollers are made hollow and a spacer is passed through each. This, however, does not in any way alter the basic principle of the bearing. Another type of roller bearing widely adopted in industrial work uses rollers each of which is a helix wound from a rectangular steel rod. Alternate rollers are wound right and left hand so that there is no possibility that they will wear either the raceway or shaft unevenly.

Several advantages are claimed for this type of bearing. In the first place, the rollers, although hardened and ground, are somewhat flexible. As a result, instead of obtaining line contact between roller and raceway or between roller and shaft, which is alone possible theoretically, surface contact, or what might be termed strip contact, is actually obtained. The flexibility of the rollers also permits them to accommodate themselves to any slight inequalities of either shaft or race.

MAY TAKE END AS WELL AS RADIAL STRESSES

More lubricant can be packed into a bearing of this kind than into one containing solid rollers, and the helical roller carries and distributes this lubricant efficiently throughout all parts of the bearing. Furthermore, this bearing, it is claimed, can absorb more dirt than a solid-roller bearing of the same size and still function satisfactorily. Of course, every precaution is taken to keep foreign material out of anti-friction bearings but the undesired sometimes happens, and dirt and dust find their way into a journal box no matter how thoroughly it may be protected.

All the bearings thus far described are intended to receive radial stresses only; any end thrust that may develop must be absorbed by some other part than the bearing itself. A type of roller bearing intended to take both radial pressure and end thrust is shown in Fig. 3.

In this bearing the rollers or the active portions thereof are not right cylinders but the frustums of cones. These rotate between male and female cone

FIG. 3

Roller Bearing that Takes End Thrust

In this bearing the rollers are frustums of cones that roll between male and female cone-shaped sleeves pressed onto the axle and into the wheel hub respectively.

raceways or sleeves pressed upon the shaft and into the wheel hub respectively. It will be apparent at once that any end thrust exerted upon the flange of a mine-car wheel will be transmitted to the axle not through the end of the hub or the wheel cap but through the roller bearing. The axle in the illustration to which reference has been made, except where it passes through the wheel, may be square and bolted securely to the car body. The wheel thus will be free to revolve without end play and without touching anything except the rollers and the dirt-excluding felt washer. Wear to which all bearings are subject may be taken up from time to time as it develops.

So much for the roller bearing. Though the ball bearing possesses certain obvious advantages, it as a rule has been considered too expensive for installation on mine cars. It has, however, found a fairly extensive use on mining locomotives. Here it is employed mainly on the armature shaft although to a lesser extent upon driver journals.

In the ball bearing, hardened steel balls ground to an accurate spherical shape roll between inner and outer races that are likewise hardened, ground and highly polished. Theoretically a ball has only point contact with its race. As, however, this latter member is grooved to a radius only slightly greater than the radius of the ball and as both ball and race are, within limits, thoroughly elastic, small surface contact is secured. Deformation of the ball under normal load should be such as never to exceed or even approach the elastic limit of the hardened steel. The result is that if foreign matter, except lubricant, is excluded from such a bearing, it will operate almost indefinitely without appreciable deterioration.

This latter consideration, namely, absence of wear, renders these bearings particularly applicable to the armature shafts of locomotives where they preserve indefinitely the small interval between the rotor and the pole pieces of the field. Appreciable wear on armature bearings is liable to let the armature down where the action of the field magnets or poles is unequal. Eventually such wear will permit the armature to rub on the poles and thus be quickly ruined.

The ball bearing probably reduces the friction of rotation to a greater degree than does any other type of journal intended to carry heavy loads.

The resistance that it offers to rotation is only a fraction of that offered by the ordinary bronze or babbitt-lined bearing.

Anti-friction bearings can eliminate only those power losses that are caused by friction. Thus, suppose that the resistance to the movement of a car or trip provided with plain bearings and moving over a level track is 30 lb. per ton of car or trip weight, and if mounted on anti-friction bearings, this resistance is reduced, say, to 15 lb. per ton. A locomotive of given weight therefore when moving over a level track would be capable of hauling twice as big a load mounted on anti-friction bearings as it would when mounted on plain bearings.

GRADES MAKE A DIFFERENCE IN POWER SAVED

On grades, however, conditions are somewhat different. Suppose that two trips of equal weight, let us say 100 tons, one provided with plain and the other with roller bearings are to be hauled up a 2-per cent gradient. The drawbar pull in pounds necessary with the plain bearings will be $(100 \times 30) + (100 \times 2,000 \times 0.02) = 3,000 + 4,000 = 7,000$ lb. In the case of the trip mounted on anti-friction bearings the necessary drawbar pull under the assumed conditions will be: $(100 \times 15) + (100 \times 2,000 \times 0.02) = 1,500 + 4,000 = 5,500$ lb.

Thus, on a level track the saving in power amounts to $\frac{1}{2}$, whereas in the second case assumed it amounts only to $\frac{3}{4}$. However, in any case the saving in drawbar pull is equal to the difference in frictional resistance of the two types of bearings under load on level track. Under conditions as above assumed this is 1,500 lb. In most mines such a saving is certainly worthy of consideration.

Several advantages other than decreased friction inhere to the anti-friction bearing. A recent investigation into the use of this type of bearing as applied to mine cars only, brought out the following interesting details. Of the 750,000 mine cars employed in American coal mines, 376,500 are fitted with plain bearings whereas the rest or 374,500 are equipped with roller bearings. The average lubrication interval or time between lubrications with plain bearings is 24 days, whereas with roller bearings it is 101 days. The average life of a plain bearing is 3.9 years and that of a roller bearing is 6.1 years. The average annual cost of lubricating a car (four wheels) with plain bearings is \$4.70 whereas with roller bearings this is reduced to \$1.61. Grease appears to be the lubricant all but universally applied to roller bearings, whereas, in general, oil is used with plain bearings.

ENGLAND INVESTIGATES BALL-BEARING MINE CARS

In the United States ball bearings have been little used on mine cars. Some extensive experiments have been made in England, however, with this type of bearing. In a paper read before the North of England Insti-

Fig. 4—Ball Bearings Used with Locomotive Drive Shaft

The flexible or segmented drive shaft in this illustration is mounted on ball bearings throughout its entire length. Driver journals may be of either the ball or roller type.

Fig. 5—Conveyor Belt Operating on Roller-Bearing Troughing Idlers

Some power must be expended to trough the belt and elevate the load carried. The useless horsepower or that expended in overcoming idler friction may be materially reduced by the use of anti-friction bearings in the idlers. The power saved by this means is frequently sufficient to pay handsome dividends on the increased investment.

tute of Mining and Mechanical Engineers, Dec. 9, 1922, Appleyard and Macaulay gave an estimate of the savings possible through the substitution of ball-bearing wheels for those fitted with plain bearings. These figures which are given in Table I apply to 2,000 cars with a capacity of about 2½ tons each.

The saving of \$25,077 represents over 28 per cent on a capital expenditure of \$87,480. It should also be noted that the savings of which these authors speak do not consider any economies in power whatever. Concerning this phase of the problem they say:

BEARINGS SAVE 10 PER CENT OF TOTAL CARS

“The saving in power, whether mechanical, animal or human, is so marked, especially at starting, that it can confidently be asserted that it is necessary to use only 90 per cent of the original number of cars to obtain the same service. The extra service that the cars will render is partly attained by the fact that a man can push with ease two ball-bearing cars in places where he can move only one plain-bearing car. This applies also to the haulage performed by ponies. Further, owing to the reduced friction, cars will travel by gravity down inclines where before power had to be used. Thus, with an equal expenditure of power, the number of cars required can be reduced by 10 per cent.”

Again the same authors state that by use of anti-

Table II—Data of Tests of Two Conveyors with and Without Roller Bearings

	Conveyor No. 1	Conveyor No. 2
Belt width.....	48 in.	48 in.
Conveyor length.....	381 ft. 4 in.	404 ft. 5 in.

Saving through use of roller bearings hp.....	34.	31.94
Per cent saving.....	62.9	55.5

friction bearings on a main-and-tail-rope haulage, a trip of ball-bearing cars, though they weigh 4.75 per cent more than a similar plain-bearing trip, can be moved with 8.63 per cent less power than the trip with plain bearings.

Experiments were also made to ascertain the effort necessarily expended in starting plain- and anti-friction cars of the same weight upon level track and also to determine the pull required to keep such cars in motion. Cars weighing 1,008 lb. and exactly similar, except for the bearings, were used in this test. It was found that it required 12 lb. to start a ball-bearing car, whereas 29 lb. was necessary to start one having plain bearings. Similarly, it took a pull of 6 lb. to keep a ball-bearing car moving at 2 miles per hour over a level track but required 22 lb. to keep a plain-bearing car traveling at the same rate.

SAVE POWER WHEN USED WITH BELT CONVEYORS

In its issue of Feb. 23, 1923, p. 452, the *Colliery Guardian* prints the results of some interesting tests on anti-friction bearings as applied to belt conveyors. The results of these tests are summarized in Table II.

Assuming that power costs 3c. per kilowatt-hour or 2½c. per horsepower-hour and that the conveyor operates 8 hr. per day, 300 days per year, or a total of 2,400 hr. per year, the cost of driving it per horsepower per year will be \$54. A reduction of 34 hp. in the energy needed to drive a conveyor of this kind, such as Table II shows can be accomplished, would mean, assuming an over-all motor efficiency of 75 per cent, a monetary saving of roughly \$2,450 per year.

Other savings also are possible. Thus in a new installation the rating of the driving motor as well as the weight of the belt may be reduced. In an actual instance a 75-hp. motor was installed to drive a conveyor fitted with roller-bearing idlers, whereas a 100-hp. machine would have been necessary with plain-bearing idlers. In another case a 7-ply belt was strong enough with roller-bearing idlers, but a 9-ply belt would have been necessary had plain bearings been used.

The anti-friction bearing has entered the coal industry to stay. When competition is keen advantage must be taken of any device that will lower the cost per ton. Though such bearings will doubtless withstand much abuse and neglect, they were not designed with the idea that they should logically receive such treatment. Adequate care, therefore, in their lubrication and maintenance will be amply repaid.

PROF. A. C. ALLEN, head of the department of mining engineering, West Virginia University, Morgantown, W. Va., who came to that institution from the University of Illinois, Urbana, Ill. in 1917, returns to his alma mater to become dean of the school of mines. He will complete the conduct of the regular short course in mining at West Virginia University before leaving.

News Of the Industry

Cincinnati Coal Convention and Machinery Exhibit Plans Taking Shape

Public Meeting to Be Held in Music Hall — Talks Will Be Broadcast by Radio—S. B. Crowell and H. L. Gandy to Make Addresses
—Live Topics for Discussion

Details of the program for the seventh annual meeting of the National Coal Association, which will be held in Cincinnati May 14, 15 and 16, are being perfected rapidly but have not yet been fully completed.

W. E. E. Koepler, chairman of the Committee on Arrangements, has just announced two important events. One is that arrangements are being made for a big public meeting in Music Hall, where the American Mining Congress will present its National Exposition of Mining Machinery and Mine Equipment, which will be addressed by prominent speakers whose talks will be broadcast by radio. The other is that Samuel B. Crowell, of Philadelphia, president of the National Retail Coal Merchants' Association, has accepted an invitation from the National Coal Association to address the convention on the forenoon of May 15.

The program at Music Hall will include among the speakers Harry L. Gandy, executive secretary of the National Coal Association. This meeting, to be held on the evening of May 14, will give time for delegates to visit the exposition of mining machinery and to meet the manufacturers who have displays of equipment there. Mr. Crowell will address the coal operators on "Our Customers," and it is expected that he will dwell upon the importance of a better understanding between all branches of the coal industry and the public. Mr. Crowell is an earnest advocate of the formation of a Coal Institute, regarding which various major groups of the industry have committees now at work.

Seek Lower-Cost Output

The American Mining Congress, through its secretary, J. S. Callbreath, has issued a special invitation to members of the National Coal Association to attend the Exposition of Coal Mining Equipment, which will be staged during the week of the association convention, and to join in the discussions of practical operating problems of the coal industry which will be taken up there. In a letter to Secretary Gandy, Mr. Callbreath expresses the opinion that "the outstanding problem of the coal industry is to obtain lower cost per ton of coal. The continued existence of many coal enterprises is largely

dependent upon the successful solution of this problem."

Mr. Callbreath outlines five important topics which will be discussed in Cincinnati at the National Exposition of Coal Mining Equipment and Machinery. These are:

To Discuss Live Topics

"(1) Problems of Mine Electrical Men.—The discussions of this topic will be under the leadership of Graham Bright, well-known consulting engineer, and will cover all the different phases of the effective uses of electrical power in connection with coal-mining enterprises. The leaders in this discussion are all well-known and representative operating engineers and will take up various phases of the problems of mine electrical equipment.

"(2) No subject is of greater interest to coal-mine operators than the equipment used in the preparation of coal. Colonel Warren R. Roberts, president of Roberts & Schaefer, will act as chairman of this meeting and there will be a general discussion of the new dry cleaning processes and of the various phases of primary and secondary preparation of coal.

"(3) How to increase the percentage of lump coal by better blasting methods is another topic of interest to all coal operating officials. Considerable experimentation has been done in obtaining better blasting methods and there will be an interesting discussion of this problem at Cincinnati.

"(4) An outstanding problem in obtaining greater economies in coal production is the correlation of mechanical loading with haulage and mining problems. Two afternoons of the week, Wednesday, May 14, and Thursday, May 15, will be given up to discussion of this phase of mine operation. There will be an interesting presentation and an analysis of the use of mechanical loaders in coal-mining properties.

"(5) The final discussions of Friday afternoon, May 16, will be devoted to the topic 'Necessity for Rock Dusting.' The chairman of this meeting will be John E. Jones, safety engineer of the Old Ben Coal Corporation, Chicago, a company which has been a pioneer in the installation of rock dusting as a means of eliminating dangerous explosive conditions in coal mines."

C. & O. New Equipment To Cost \$28,000,000

The Chesapeake & Ohio R.R. has placed contracts for \$28,000,000 worth of new equipment, according to an announcement by W. J. Harahan, president of the company. The orders placed include 5,500 hopper cars, 2,000 automobile cars, 600 ballast cars, 120 cabooses, 15 express cars and 100 locomotives. More than 100,000 tons of steel will be required to construct the equipment, it is said.

This will add more than 13 per cent to the coal-carrying facilities of the road, as it now has 41,820 coal cars. The Hocking Valley R.R., a subsidiary of the C. & O., owns about 12,000 coal cars.

Indiana Companies Join Merger Movement

Announcement has been made that negotiations for the consolidation of the Knox Coal Mining Co., the Howe-Coulter Coal Co. and the Panhandle Coal Co., owners of four mines in the Bicknell (Ind.) district, having a total production capacity of 1,000,000 tons annually, will be completed in a few days. The new organization, a name for which has not yet been chosen, will be capitalized for \$1,500,000. H. A. Husky, of Chicago, president of the Knox company, will head the new organization.

William Schrolucke, of Indianapolis, president of the Panhandle company, will be the vice-president and chairman of the board of directors; William H. Abraham, secretary-treasurer of the Panhandle company, probably will be secretary; W. P. Worth, treasurer of the Knox company, probably will be treasurer. Carl J. Fletcher, secretary of the Knox company, will be the general manager of the new company, and Wesley Harris will be in charge of the mine operations.

These men and another to be chosen, will form the directorate. The Howe company will not be represented on the list of officers. Mr. Fletcher said the consolidation will bring about cheaper production, the new company being able to operate part of its mines full time instead of having all four mines operate part time. Cheaper production is necessary to meet competition from non-union fields, Mr. Fletcher said. One of the mines now is being operated full time, and it is expected that another will be working at capacity in a few weeks.

Leon Besson

On April 1, Leon Besson became chief mine inspector for Kansas, succeeding James Sherwood, who returns to the service of the Associated Companies, handling mine liability insurance. The appointment of Besson by Governor Jonathan Davis has caused some political disturbance in the state because Besson is a socialist and was opposed by some good Democrats of the Governor's party. His choices of assistants are expected to cause some more disturbance.

Railways May Get Fuel Research Bureau

There has been so much confusion for years in the minds of railway fuel engineers as to the actual fuel value ratio between coals and oils that a bureau of research may be set up to make exhaustive studies of that and other fuel problems. The plan was approved a week ago at a Chicago meeting of the joint fuel conservation committee of the American Railway Association and the International Railway Fuel Association. The plan goes now to the American Railway Association's directorate for approval.

Other problems to be submitted to the research director for solution relate to the utilization of lignite coal, results obtained from relative grades of coal in relation to the cost involved, spark losses, the effect of electrification on fuel consumption per ton-mile and per passenger car-mile, the economic aspects of coal storage, influence of locomotive design on fuel economy, introduction of turbine-driven and Diesel motor type locomotives, etc.

At the meeting in Chicago the committees decided upon the text of a questionnaire to be submitted to all the railroads for the purpose of determining actual progress toward fuel conservation and what fuel-economy practices have been generally adopted. The first three booklets of the American Railway Association's manual on fuel and related economies as compiled by the International Railway Fuel Association also were approved at this meeting and will soon be available for distribution to the railways.

Mine Inspectors Prepare For Big Meeting

Safety in coal mines, viewed from many slants will be much at the fore in Cincinnati the week of May 12 not only because the American Mining Congress will pay attention to it but also because the Mine Inspectors' Institute of America will be in annual session there from the 14th to the 16th with a program that will be devoted 100 per cent to safety. Men from many states whose daily work is to make mines safe will assemble in the Sinton Hotel.

An official announcement by James Sherwood, president, of Pittsburg, Kan., says that all members of the Institute and all state or provincial mine inspectors in America are invited to study the program and either be present prepared to talk on one or more of the subjects or mail Mr. Sherwood papers they may write. The Institute is going to devote a good deal of time to the question of standardizing the safety laws of the country. So a committee composed of Dr. J. J. Rutledge, chief mine engineer for the Maryland Bureau of Mines; James Dalrymple, chief mine inspector for Colorado, and R. M. Lambie, chief inspector for West Virginia, will meet in Cincinnati two days in advance and prepare an outline for a standardization discussion at the forthcoming convention.

The outline of other subjects to be discussed follows:

(1) Qualifications of coal-mine inspectors, both as to practical experience and technical knowledge. James Dalrymple, chief, Colorado.

(2) Closed lights in all coal mines. Dr. J. J. Rutledge, chief, Bureau of Mines, Maryland.

(3) Systematic timbering. R. M. Lambie, chief, West Virginia.

(4) How lives and property may be best protected by inspection. V. E. Sullivan, inspector, West Virginia.

(5) Guarding and protecting of electrical wiring and equipment in coal mines. Jerome Watson, chief, Division of Mines, Ohio.

(6) Precautions and suitable pillars between working mines and abandoned mines filled with water. J. E. Holland, chief, Iowa.

(7) Should coal be shot from the solid under any conditions in any state? And why? G. B. Butterfield, general manager, Associated Companies, Connecticut.

(8) First-aid and safety organiza-

Walsh Favors Rock

Dusting

Joseph J. Walsh, State Secretary of Mines, of Pennsylvania, has called a meeting of all the inspectors in the Pittsburgh district, to be held late this month, to urge the adoption of rock dusting to prevent coal-dust explosions in bituminous mines. In the past explosions of air heavily laden with coal dust has been responsible, says a department statement, for some of the most disastrous explosions in the soft-coal mines.

F. G. Wilcox

Appointed a director, president and general manager of the Price-Pancoast Coal Co., the West End Coal Co. and the Melville Coal Co. in succession to the late William L. Allen. Mr. Wilcox has had 20 years' experience in the coal industry, having joined the Hillside Coal & Iron Co., in 1904, when he was graduated from Lafayette College. He became associated with the Price-Pancoast Coal Co. in 1918.

tion. H. H. Warner, senior inspector, Associated Companies, Colorado.

(9) The necessity of getting the proceedings of the annual report of the meeting of the Mine Inspectors' Institute of America into the hands of the mine workers and mine managers. J. E. Roberts, chief, Missouri.

(10) The relation of accidents to lack of discipline and enforcement of safety rules. Prof. G. E. Abernathy, State Mining College, Pittsburg, Kan.

Low Bids for Navy Coal

Bids opened by the U. S. Shipping Board at New York on April 18 for furnishing and delivering alongside vessels in that harbor 1,065 gross tons of bituminous coal equal to either Pool 71 or 9 brought tenders from seven coal firms with prices ranging from \$4.23 per gross ton to \$4.97, or on a basis of \$1.03 to \$1.70 per net ton f.o.b. mine. The bidders and prices submitted were: Whitney & Kemmerer, \$4.85 per gross ton, f.a.s.; H. B. W. Haff, \$4.75; B. J. Lynch, \$4.97; W. A. Marshall & Co., \$4.62; Rhodes Fuel Corporation, \$4.54; Flack & Son, \$4.44, and Seiler Coal Co., \$4.23.

Brazil Block Operators to Sign Union Contract

The scale committee of the United Mine Workers of District No. 8, with headquarters at Brazil, Ind., and the Brazil Block Coal Producers' Association are holding a joint meeting to sign up a new mining contract. It is understood the contract is agreeable to all parties, but the delay in signing has been caused by failure of the wagon-mine owners to get together and complete the organization of their association.

Growth of West Virginia Coal Fields Laid to Freedom from Union Domination

B. M. Clark, president of the Association of Bituminous Coal Operators of Central Pennsylvania, takes issue sharply with some of the statements of John Brophy, president of District No. 2, United Mine Workers, made in reply to comment by Mr. Clark on the recent wage agreement. Mr. Clark says:

"The assertion made by the United Mine Workers that 'for a remedy they [the operators] suggest the same old panacea they have been offering for the past thirty years—lower wages' is not in accord with the facts. During the past thirty years and since I have been president of the operators' association, wages in the union mines have increased over 240 per cent. This speaks for itself.

"The present wage agreement, signed for a period of three years, will be carried out as faithfully by the operators (unless the United Mine Workers revise it) as all preceding agreements we have signed with them have been carried out during the past twenty-five years. The matter of changes in the contract rests entirely with the union.

"It is my opinion, however, that economic forces operating today will exercise a compelling influence upon the judgment of the United Mine Workers just as these forces will influence the judgment of the rest of us during the next three years. The law of supply and demand operates in the coal industry. People will buy coal or any other commodity at the lowest price obtainable. That section of the coal industry or any other industry that cannot produce at a cost below the market price will go out of business. Central Pennsylvania cannot produce coal at the selling prices in the market today. The effect of the law of supply and demand is as inevitable as time.

Says Overdevelopment Is Serious

"Overdevelopment of the bituminous-coal mining industry is not questioned. The extent of that overdevelopment, however, is a question upon which experts disagree. I am not sure that we can produce twice as much coal as we need. The overdevelopment, however, is sufficient to be serious for those who have their money invested in coal mining.

"Overdevelopment will continue to increase in the non-union sections of the country as long as the union is able to maintain such a high wage schedule in the union fields as to permit the non-union operators to make profits on selling prices that are below the cost of production in the union fields. That is the condition now. The policy of the United Mine Workers accounts in part for the overdevelopment of the industry. The development of the non-union coal fields of West Virginia is one of the industrial marvels of the past twenty years. This development has taken place during the period of growth and increase of power of the United Mine Workers in the older fields. It cannot be seriously questioned that the great mining development of West Virginia

is due to its policy of employing non-union labor.

"The real facts as to actual cars of coal loaded in the central Pennsylvania district as compared with the Pocahontas and New River districts of West Virginia are as follows: In January, 1923, Pocahontas loaded 80,725 cars; in January, 1924, 106,403, or an increase of 25,678 cars. In January, 1923, central Pennsylvania loaded 72,570 cars; in January, 1924, 59,402, or a decrease of 13,168 cars. In February, 1923, Pocahontas loaded 82,484 cars; in February, 1924, 117,769, or an increase of 35,285 cars. In February, 1923, central Pennsylvania loaded 70,006 cars; in February, 1924, 62,757, or a decrease of 7,249 cars. From March 1 to 15, 1923, Pocahontas loaded 68,785 cars; the same period, 1924, 87,970, or an increase of 19,185 cars. From March 1 to 15, 1923, central Pennsylvania loaded 54,768 cars; in the same period, 1924, 46,011, or a decrease of 8,767 cars.

Pocahontas Forges Ahead

"During these months in 1923 business was good in the coal industry and everybody had orders. The results for that period show the relation between these fields when competitive conditions are equal. The increase in car loadings in the Pocahontas district and the decrease in the central Pennsylvania district show accurately the results of the present competitive situation. In a falling or depressed market up to March 15, this year, the Pocahontas district has increased its loadings approximately 35 per cent over its loadings during a period of good demand for coal, whereas the central Pennsylvania district shows a decrease in its loadings in 1924 as compared with 1923 of 15 per cent. The weekly car loadings in central Pennsylvania have often exceeded 24,000. For the week ending April 5 the total loadings in the central Pennsylvania district were but 8,975, the lowest output on record during a period of no strike. The business is going to the non-union fields of West Virginia."

Miners Boom Pinchot for Presidential Delegate

Governor Pinchot has made public a telegram received from the miners in District No. 2, United Mine Workers, endorsing his candidacy for delegate at large to the Republican National Convention. Resolutions passed by the miners' executive board lauded the Governor for his "fairness to labor" and urged every mine worker to record his approval of the Governor's labor policy by voting for Mr. Pinchot.

The telegram, sent from Clearfield, Pa., reads: "District No. 2 executive board passed following resolution today: 'In view of Governor Gifford Pinchot's fairness to labor, the executive board of District No. 2, United Mine Workers of America, ask mine workers and their friends who are Republicans to vote for him in the primary election, April 22, for delegate at large to the Republican National Convention.'"

All Quiet on Straight Creek

Things have been so quiet at Pineville and at the Liberty Coal & Coke Co. plant at Straight Creek, Ky., that the military protection has been reduced to about two companies, there having been no shooting or other disturbances for a week. Two companies have been withdrawn.

After failure to accomplish anything in a conference April 12 with union leaders and company officials regarding arbitration Governor Fields arranged to go to Straight Creek for further conferences, to include the company's own workers, but he has postponed his trip from day to day.

Federal Judge A. M. J. Cochran has granted a preliminary injunction enjoining the International union and its officers, the district union and its officers and the local union and its officers from interfering with officers, agents or employees of the company in the performance of their duties.

Picking Tables of Clearfield Bituminous Corporation, Rossiter, Pa.

Large pockets are provided for the removal of the refuse contained in the coal.

Coal Bids for Schools of New York Opened

Bids opened by the Board of Education of New York City on April 14 for furnishing, delivering, storing and trimming about 160,000 net tons of hard and soft coal to the school houses and offices of that body for the period ending April 30, 1925, showed a variety of prices ranging from \$10.61 for broken coal in the Borough of Manhattan to \$13.75 for chestnut in Richmond Borough. The amounts required are 40,900 tons of broken; 99,050 tons No. 1 buckwheat; 7,440 tons bituminous mine-run; 6,880 tons pea coal; 1,900 tons egg; 2,440 tons stove coal and 140 tons chestnut size. There were 17 bidders, some of whom bid only on individual lots in some of the boroughs.

In Manhattan the tenders on broken and egg coals ranged from \$10.61 to \$12.83 per ton; stove and chestnut, \$10.68 to \$12.83; pea coal, \$7.36 to \$9.12; No. 1 buckwheat, \$5.22 to \$6.53; soft coal, \$5.24 to \$6.46.

Bronx—Broken coal, \$10.66 to \$12.48; egg, stove and chestnut \$10.72 to \$13.48; pea coal, \$7.30 to \$9.12; No. 1 buckwheat, \$5.26 to \$6.53; soft coal, \$5.14 to \$6.46.

Brooklyn—Broken, \$11.23 to \$12.42; egg, stove and chestnut, \$11.37 to \$12.42; pea coal, \$6.98 to \$9.35; No. 1 buckwheat, \$4.98 to \$6.36 and soft coal, \$5.14 to \$6.49.

How New Immigration Law Affects Old Quotas

Washington, D. C., April 19.—The Senate passed the immigration bill tonight by a vote of 62 to 6 after discussion lasting about seven hours. The bill restricts immigration to 2 per cent on the basis of the 1890 census, which cuts the total quota from 357,801 to 161,990. The Senate adopted an amendment giving preference in admissions to persons skilled in agriculture, but in other salient features the Senate bill is in substantial accord with the Johnson bill as passed by the House. The measure will now go to conference and early agreement is expected. Predictions among Senators were that the President would not veto it. The annual quotas from principal countries under the old law as compared with those permitted under the new are as follows:

Country	Present Law	New Bill
Great Britain and Ireland	77,342	62,558
Germany	67,607	50,229
Italy	42,057	3,989
Poland	30,979	8,972
Russia	24,405	1,892
Sweden	20,042	9,661
Czechoslovakia	14,357	1,973
Norway	12,205	6,553
Rumania	7,419	731
Austria	7,342	1,090
Jugoslavia	6,426	835
Hungary	5,747	588
France	5,729	3,978
Denmark	5,619	2,882
Finland	3,921	245
Switzerland	3,752	2,181
Netherlands	3,602	1,737
Greece	3,063	135
Turkey	2,654	123
Lithuania	2,622	402
Portugal	2,465	574
Belgium	1,563	609
Latvia	1,540	217
Estonia	1,348	202

Lake Navigation Opens

The freight navigation season for 1924 on the Great Lakes was opened April 19 with the passage through the Soo locks of the steamers Theodore Wickwire Jr. and Frank H. Goodyear, laden with coal for Sault Ste. Marie, Ont.

Queens—Broken, \$11.23 to \$12.70; egg, stove and chestnut, \$11.37 to \$13.20; pea coal, \$6.98 to \$9.50; No. 1 buckwheat, \$5.13 to \$6.48, soft coal, \$5.14 to \$6.45.

Richmond—Broken, \$12.09 to \$13.50; egg, \$12.68 to \$13.75; stove and chestnut, \$12.75 to \$13.75; pea coal, \$7.14 to \$9.95; No. 1 buckwheat, \$5.45 to \$7.14. soft coal, \$6.19 to \$7.14.

For delivering 3,600 tons of soft coal, mine run to the Parental School in Queens the bids ranged from \$5.14 to \$5.40 per ton.

Union Rebels Still Fighting For Alex Howat

The struggle to get Alex Howat back into the Mine Workers union still has some life. The radical voices were scheduled to be lifted up again at the convention of Illinois Subdistrict No. 4, at Auburn, Ill., on the 23d. John Watt, secretary of the subdistrict, said that a resolution for a special International union convention to reconsider the Howat case would be passed. He asserted that the demand for such a special convention will be backed by Illinois, Michigan, Kansas, Washington, Montana, Wyoming, Nova Scotia and Vancouver.

Dissatisfaction of some Illinois mine workers with the new three-year union agreement with operators also will break into voice, he said. A good deal of dissatisfaction exists throughout the state because the miners think they are going to get very little work under such an agreement. They expect nearly non-union districts to win much of Illinois' markets.

Railroads Consume 9,432,000 Tons of Coal in January

Class 1 railroads of the United States consumed 9,432,000 net tons of coal during January, compared with 8,647,000 tons in the preceding month and 10,375,000 tons in January, 1923, according to a report by the Bureau of Statistics of the Interstate Commerce Commission covering 176 steam roads. During 1923 these roads consumed a total of 109,442,000 tons, compared with 96,077,000 tons in 1922. The delivered cost of coal consumed in road service in January was \$3.25 per net ton, compared with \$3.27 in December and \$3.73 in January, 1923.

Consumption of fuel oil by the roads during January totaled 188,842,000 gallons, compared with 184,722,000 gallons in the preceding month and 150,297,000 gallons in January, 1923. During 1923 the roads consumed 1,980,015,000 gallons, compared with 1,556,090,000 gallons in 1922.

Roads Break Traffic Records

Two new high records were established by Class 1 railroads of the country during February, according to the Bureau of Railway Economics. They handled the greatest volume of freight traffic, measured in net ton miles, carried during any February in history and the average daily movement per freight car for the month was 27.4 miles per day, the highest for any February on record.

Freight traffic in February amounted to 35,962,421,000 net ton miles, an increase of 3,332,065,000 or 10.2 per cent, over the same month last year, and an increase of 3,010,289,000 net tons miles or 9.1 per cent, over February, 1920, which was the previous record month. Compared with 1922, it was an increase of 7,511,508,000 net ton miles, or 26.4 per cent. For the months of January and February alone, freight traffic amounted to 70,463,134,000 net ton miles, the greatest volume ever handled by the railroads during the first two months in any year.

In attaining a daily average movement of 27.4 miles per freight car, the railroads of the country in February exceeded the same month last year by 2.6 miles, and February, 1920, by 5.1 miles. The average also exceeded that for January this year by 2.4 miles.

The average load per freight car in February was 27.6 tons, a decrease of 0.6 ton compared with the same month last year and 0.7 of a ton decrease compared with February, 1920.

Pinchot Publishes His Coal Exploits

Governor Pinchot of Pennsylvania has been issuing weekly statements to the newspapers giving in detail his own account of his administration. In his release of April 10 he tells of the settlement of the anthracite strike of last summer.

"When I came into office," he stated, "the whole state was suffering from a shortage of coal. Houses were poorly heated and disease increased so greatly that 6,000 persons lost their lives who probably would have been living today had there been no shortage of coal. That struggle between miners and operators cost \$30,000,000.

"Last fall the state and the nation were confronted with the probability of another coal shortage. Thereupon representatives of miners and operators were invited to Harrisburg, the public necessity of preventing a strike was laid plainly before them, and when the deliberations were over the strike had been settled. Thereby those who could not otherwise have got coal were enabled to secure it, while the few who might have got it in spite of the strike secured it at far less cost than they would otherwise have had to pay. Another heavy loss of life, comfort and money was thus averted."

U. S. Commerce Chamber to
Discuss Natural Resources
And Trade Associations

Natural resources and trade associations and their activities are among the score or more of topics of interest to the coal industry that will be discussed at the annual meeting of the Chamber of Commerce of the United States, to be held at Cleveland, Ohio, May 6-8. Other subjects that will be taken up include taxation, transportation, industrial relations, industrial mobilization, immigration and national economy.

The subject of natural resources will be considered at a group meeting to be held at 2 p.m., May 7, in the ballroom of the Hollenden Hotel. At this meeting, which will be held under the auspices of the Chamber's Natural Resources Production Department, of which W. DuB. Brookings is manager, James R. Garfield, former Secretary of Interior, will speak on "Government Control of Natural Resources"; Paul Armitage, of New York, chairman of the Tax Committee of the American Mining Congress, will discuss "Tax Problems in Relation to Reserves and Depletion of Natural Resources," and Goldthwaite H. Dorr, of New York, formerly counsel for the Bituminous Operators' Special Committee, appointed to co-operate with the U. S. Coal Commission in investigating and determining the facts about the bituminous-coal industry, will read a paper on "Trade Association Problems Relating to Natural-Resource Industries."

Trade Associations Prove Magnet

Three separate proposals concerning trade associations have been submitted by member organizations of the National Chamber for consideration, as follows:

The Memphis Chamber of Commerce proposes that the National Chamber advocate creation of a commission which would define the rights of trade associations and their members in all respects, including their rights to discuss operating expense, sources of supplies for materials, prices, trade competition, etc. A study of anti-trust laws and of the Federal Trade Commission's powers and activities would be included. The purpose of this is to establish recognized principles which would remove handicaps under which trade associations now operate, through fear that they may violate some law, rule or regulation and be called before a commission or the courts upon a criminal or civil charge, the existence of which, regardless of the merits, is detrimental.

The Southern Central Division of the National Chamber recommends that all possible steps be taken to effect elimination of obstacles and uncertainties which interfere with the most effective carrying out by trade associations of their function of disseminating information.

The National Coal Association proposes that the President of the United States be asked by the National Chamber to direct the Attorney-General to

Charles E. Karstrom

Here is a man who is becoming a more important figure in the Illinois coal industry. He is now president of the Harrisburg Colliery Co. and vice-president of the Shoal Creek Coal Co. In March, *Coal Age* reported the purchase of the Harco mine in Saline County, Illinois, by interests affiliated with Big Creek Coals, Inc., a concern which operates other mines in Saline County and which, by reason of the purchase, now operates the Harco mine. Mr. Karstrom is 36. He began his career in the coal business by entering the employ of Big Creek Coals, Inc., and grew in that concern until he was made vice-president. In 1920 he became vice-president of the Shoal Creek Coal Co. His offices are in Chicago.

institute a test case of such a character that it will determine the legal status of activities of trade associations in gathering and giving to the public statistical information concerning production, distribution, cost and prices when no improper private use of such statistical information by the association or its members is alleged.

Lehigh Section A.I.E.E. Holds
Anthracite Session

Members of the Lehigh section of the American Institute of Electrical Engineers met April 11 and 12 in Wilkes-Barre for another session in the anthracite region. On the first evening papers were read by Carl P. Brodhun and Lawrence W. Bevan on electric cables and wire ropes, a feature of the session being motion pictures of the Ashley Planes. Here the Jersey Central R. R. hoists in 24 hours 37,200 tons of coal to an elevation of over 1,000 ft. Henry Schroeder, of the Edison lamp works, gave an illustrated lecture on the history and manufacture of electric lamps.

On Saturday morning the members and guests of the society were entertained at the Hazard Manufacturing Co.'s plant, where they were personally conducted through the plant and shown every detail of the manufacture of electric conductors and haulage ropes. In the afternoon the party journeyed to Scranton and a similar inspection tour was made through the General Electric lamp works.

French Coal Output in 1923
Near Pre-War Level

French coal mines in 1923 produced 38,576,215 metric tons (37,714,393 tons of coal and 861,822 tons of coke) compared with a production of 41,000,000 metric tons in 1913 (40,501,000 tons of coal and 793,000 of lignite). Immediately after the war, as a consequence of German systematic devastation of the mines of the northern districts, the output was reduced by about 50 per cent. In 1919 it did not quite reach 23,000,000 tons (21,567,000 tons of coal and 909,757 of lignite). Since then the output has been steadily increasing, and the gain which was not halted by the great economic crisis of 1920-21, was especially marked in 1923.

Coal Output by French Mines
(In metric tons, of 2,204.6 lb.)

Years	Coal	Lignite
1913.....	40,501,000	793,000
1919.....	21,567,000	909,757
1920.....	24,303,228	971,076
1921.....	28,240,887	735,608
1922.....	31,940,000	758,000
1923.....	37,714,393	861,822

Such progress was made possible only through the most active, persistent prosecution of reconstruction of the mines destroyed in 1918 by the Germans. In 1923 the output of the mines of the departments of Nord and Pas-de-Calais amounted to about 20,900,000 tons, the figures for preceding years being shown in the following table, in metric tons:

1913.....	27,000,000
1919.....	7,000,000
1920.....	9,700,000
1921.....	13,500,000
1922.....	15,400,000
1923.....	20,900,000

French Production of Metallurgical Coke
(In thousands of metric tons)

	1921	1922	1923
Coke produced in coke ovens of metallurgical plants.....	1,039	1,509	2,310
Coke produced in the coke ovens attached to the mines.....	745	1,031	1,986
Total.....	1,784	2,540	4,286

French Coal and Coke Consumption
(In thousands of metric tons)

	Production	Imports	Exports	Consumption
1919....	21,567	22,262	590	43,239
1920....	24,303	28,041	465	51,879
1921....	28,241	22,719	2,192	48,768
1922....	31,940	27,474	2,567	56,847
1923....	37,714	29,987	2,772	64,839

Two Illinois Operators Are
Back in the National

Two important Illinois coal-operating concerns recently rejoined the National Coal Association. They are the Chicago, Wilmington & Franklin Coal Co. and the J. K. Dering Coal Co. These are the first to re-enter the association since the disaffection which was started more than two years ago by the withdrawal of the Peabody Coal Co. Later the withdrawal of the State of Illinois was complete. The general complaint was that the National cost more than it was worth. The value of having national representation, however, has since been realized by some Illinois operators. Also the National has removed some of the objections raised against its expensiveness. But there is no landslide of Illinois back into the association yet.

By J. W. POWELL
Contracting Engineer, Welch, W. Va.

CONCRETING the main hoisting shaft of a coal mine without in any way interfering with operations is a job that is not without its difficulties, but the following description of the concreting of the main hoisting shaft of the E. E. White Coal Co.'s mine at Glen White, W. Va., shows that attacked in the right way the work can be done effectively and without waste of effort. This shaft, which is 13x31 ft. in outside dimensions and 307 ft. deep, contained three compartments. It was originally timbered throughout with 8x10 oak timbers. End and side plates were backed with 2-in. oak lagging placed skin to skin. Sets were placed on 5-ft. centers and the buntons were 8x10-in. timbers with the 8-in. face vertical. The punch posts on the corners were 10x10 in. and 8x10 in. where they supported the cross buntons of the compartments. In order to render the shaft capable of accommodating larger equipment which it is intended to install later, the inside dimensions were increased 8 in., both in length and breadth.

Preparation for concreting was begun from the top of the water ring midway in the shaft and carried upward to the concrete previously placed below the shaft collar. All lagging, back filling and loose rock on the shaft ribs were taken out and the ribs carefully trimmed. Next, the sides of the shaft were thoroughly washed down with water from a hose which was connected to the water system at the top of the shaft, great care being taken to see that all mud and slime, which had accumulated upon the ribs during past years was thoroughly removed. This was considered a highly important portion of the work, for without it a proper bond could not be obtained between the concrete and the walls of the shaft.

After a section of the shaft, equal in length to eight or ten sets of timbers, had been prepared in the manner above described, a foundation platform was built as well as the first 5-ft. form. This was closely calked to prevent the concrete from leaking when pouring was begun. The forms were built in 5-ft. sections and made of 2-in. planks surfaced on one side. Five sets of

forms were built, and when the last was placed the first was transferred from the bottom to the top, the wall being continued upward in this manner.

Where springs of water were encountered in the walls of the shaft 1½ in. drain pipes were placed to relieve the pressure while the concrete was setting. These pipes were covered with a ball of cotton waste tied over their inner ends next to the rib of the shaft so as to prevent blockage by the concrete. This waste was afterwards fished out through the pipes by means of a hook, thus allowing the water to flow freely. A sleeve was placed on the inside end of the drainage pipe so that it could be plugged after the concrete had become set and firm.

In the accompanying illustration, A shows a general plan and vertical section of the shaft, as well as the method by which the shaft was concreted. A ¾-yd. gasoline-driven concrete mixer was employed in this work. This was connected by means of a sheet iron chute about 4ft. long to the top of a 4-in. iron pipe which was suspended in the shaft by a ½-in. cable, the upper end of which was clamped to the head-frame of the shaft. Every 40 ft., or every two pipe lengths, the pipe was attached securely to the cable by means of a specially designed clamp. Other-

wise the pipe was allowed to swing freely in the shaft. By this means, it could be pulled easily over to any point desired for the pouring of the concrete.

A detail of the attachment of the rope to the pipe is shown at C, the specially designed deflection box for the concrete being shown at B. With this combination of a loose swinging pipe and a deflection box, it was possible to eliminate entirely all chutes for conveying the concrete behind the forms. In the illustration, D shows a section of timbers removed and faced with concrete flush with the finished walls of the shaft.

A 1:2:4 mixture was used in this work, crushed limestone up to the size of 2 in. being used as the coarser aggregate. Reinforcement consisted of ½-in. distorted iron rods placed 2 ft. apart vertically and ¾-in. rods spaced 12 to 16 in. apart horizontally.

On top the crew employed in wheeling and mixing the concrete consisted of seven men including the bell boy. This number was excessive and could have been reduced to four if the material had been placed close to the mixer. As the tippie was kept in daily operation, however, it was necessary to unload the concrete materials from railroad cars at a point from 100 to 250 ft. away from the mixer. Even under these circumstances, however, as many as 200 batches were sometimes placed in eight hours.

Within the shaft five men were employed. Two of these were engaged in spading the concrete behind the forms; the other three built the forms, placed the reinforcement, repaired the central wall and did like work. The placing of concrete was performed under somewhat adverse conditions, that is, be-

Cost of Placing Concrete in Shaft Lining—Months of August and July

Labor Costs Operation	Hours	Hourly Wage Rate	Total Labor Cost	Cost per Cu. Yd.	
				Aug.	July
Building forms.....	176	@ 95c	\$167.20	\$0.90	\$0.89
Spading concrete.....	130	@ 95c	123.50	.66	.78
Mixing concrete.....	62	@ \$1-\$62	328.70	1.77	2.12
Mixing concrete.....	381	@ 70c-266.70			
Total labor.....			\$619.40	\$3.33	\$3.79
Material Costs				Cost per Cu. Yd.	
	Quantity	Price	Total Cost	Aug.	July
Cement.....	276.25 bbls.	@ \$3.30	\$911.62		
Sand.....	81.4 cu. yd.	@ 3.07	249.89		
Limestone.....	162.8 cu. yd.	@ 2.50	407.00		
Reinforcement.....	3,000 lb.	@ 3c	105.00		
Total.....			\$1,673.51	\$9.04	\$9.06
Summary					
Total cost of material per cu. yd.....				Aug. \$9.04	July \$9.06
Total cost of labor per cu. yd.....				Aug. 3.33	July 3.79
Total cost (labor and material) per cu. yd.....				\$12.37	\$12.85
Total quantity of concrete placed, August 183 cu. yd.					

tween the hours of 5:30 p.m. and 2:30 a.m. It was necessary to have the shaft in operating condition by 3 a.m., which was the time when the firebosses entered the mine to make their regular inspections. The work of concreting was nevertheless accomplished without interfering with the operation of the mine, or delaying it more than 30 min. during the entire job.

Some of the company officials questioned the quality of the concrete fearing that the aggregates would become segregated while being poured to so great a depth through a pipe so small as 4-in. diameter. It was demonstrated, however, that this did not impair in the least the quality or appearance of the finished concrete. The deflection box at the bottom of the pipe sprayed the concrete behind the forms where it was thoroughly spaded into place by the men stationed at this point. The concrete was mixed wet enough to allow its free movement into place behind the forms. This also resulted in a fine finish of the face because of the thorough spading.

The time that should be allowed for concrete so placed to set was somewhat

of a question. It was demonstrated by actual experiment at a point 300 ft. below the shaft collar that when forms were removed 24 hr. after the pouring of the concrete, this material was quite solid. In pouring the lower portion of the shaft, therefore, only three sets of forms were used.

The accompanying table is a report of the labor and material costs during the month of August. It represents approximately the average cost throughout the entire operation of lining the shaft.

Relative Dangers of the Coal Seams of Pennsylvania

Studies have been made by R. N. Hosler, into the relative hazard of the coal seams of Pennsylvania. The details of this inquiry may be found in "Statistical Analysis of Coal-Mine Accidents in Pennsylvania—1916 to 1922 Inclusive," published by the Pennsylvania State Government at Harrisburg, Pa. Arranging the seams of the state according to the frequency of fatalities the results are as in Table I:

Table I—Ordinary Inside Fatality Rate Per Million Tons Production

Seam	Fatality Rate
(1) Sewickley	3.44
(2) Double Freeport	3.03
(3) Upper Kittanning	2.95
(4) Lower Freeport	2.77
(5) Clarion-Brookville	2.61
(6) Pittsburgh	2.47
All seams	2.47
(7) Lower Kittanning	2.29
(8) Upper Freeport	2.16
(9) Middle Kittanning	2.11

It will be seen that the Clarion and Brookville beds are classed together and that the Double Freeport is separately classified. It is interesting to note how the Pittsburgh and Lower Kittanning, the former considered a relatively dangerous bed and the latter a relatively safe one have by care in the one, possibly, and less care in the other become close neighbors in the column of hazards. Only 7,588,000 of Middle Kittanning coal was mined in the seven years as compared with 1,054,452,000 tons in the nine beds. The Middle Kittanning seam is the least hazardous and least mined of any.

The seams may also be arranged as to frequency of fatalities based on one thousand 2,000-hour workers, see Table II.

Table II—Ordinary Inside Fatality Rates Per One Thousand 2,000-Hour Workers

Seam	Fatality Rate
(1) Double Freeport	3.97
(2) Sewickley	3.64
(3) Upper Kittanning	3.22
(4) Pittsburgh	3.15
(5) Lower Freeport	2.85
All seams	2.83
(6) Upper Freeport	2.27
(7) Clarion-Brookville	2.26
(8) Lower Kittanning	2.21
(9) Middle Kittanning	2.14

The expression, "ordinary fatality" denotes a fatal accident that occurs to not more than a predetermined number of persons at any one time. It may be noted that the returns are to some extent of less value because they do not differentiate accidents from falls from those which occur from other causes, such as gas. A man working 250 days and eight hours each day will work 2,000 hours. That length of time has been chosen as the basis for computing Table II.

Light at the Working Face

Concentration of forces at the working face increases the need, and decreases the cost per ton, of supplying stationary electric lighting at the mine face or the roadways adjacent to it. Sam Mavor, of Glasgow, addressing the Mining Institute of Scotland, at Heriot-Watt College, Edinburgh, said that with the intensive system of mining in which coal cutters and conveyors were used jointly it was "not only practical but economical to light the working places." "It certainly," he added, "greatly facilitated the work in hand and in mines where open-flame lamps previously were used it contributed to the comfort and efficiency of the men." With more intensive mining the installation of a lighting system will come almost automatically as an indispensable adjunct to successful operation.

Method Devised for Concreting in Between Periods of Operational Activity
